CYW89820

Bluetooth 5.0 SoC for Automotive Applications

CYW89820 is a monolithic, single-chip, Bluetooth 5.0 compliant, standalone baseband processor SoC with an integrated 2.4 GHz transceiver.

Manufactured using the industry's most advanced 40 nm CMOS low-power process, the CYW89820 employs the highest level of integration, eliminating all critical external components, and thereby minimizing the device's footprint and costs associated with the implementation of Bluetooth solutions.

Integrating a transceiver, baseband processor, Arm® Cortex®-M4, and application Flash memory on a single die provides the capability to replace function-specific devices with a single design that offers all Bluetooth modes of operation.

The CYW89820 brings the latest Bluetooth technology to automotive applications and offers automotive Grade 2 (–40 °C to +105 °C) ambient operating temperature performance. The CYW89820 is tested to Automotive Electronics Council AEC-Q100 environmental stress guidelines and is manufactured in ISO9001 approved and TS16949 certified facilities.

Features

- **Bluetooth Sub-System**
 - Complies with Bluetooth Core Specification version 5.0
 - QDID: [151200](#)
 - Declaration ID: [D043201](#)
 - Includes support for BR, EDR 2 Mbps and 3 Mbps, eSCO, Bluetooth LE, and LE 2 Mbps.
 - Programmable TX Power up to 11.5 dBm
 - Excellent receiver sensitivity (–94 dBm for Bluetooth LE 1 Mbps)
- **Microcontroller**
 - Powerful Arm® Cortex®-M4 core with a maximum speed of 96 MHz
 - Bluetooth stack in ROM allowing standalone operation without any external MCU
 - 256-KB on-chip Secure Flash
 - 176-KB on-chip RAM
 - Bluetooth stack, Peripheral drivers, Security functions built into ROM (1 MB) allowing application to efficiently use on-chip Flash
 - AES-128 and True Random Number Generator (TRNG)
 - Security functions in ROM including ECDSA signature verification
 - Over-the-air (OTA) firmware updates
- **Peripherals**
 - 17 GPIOs
 - I2C, I2S, UART, and PCM interfaces
 - Quad-SPI interfaces
 - Auxiliary ADC with up to 14 analog channels
 - General-purpose timers and PWM
 - Real-time clock (RTC) and watchdog timers (WDT)
- **Power Management**
 - On-chip power-on reset (POR)
 - Integrated buck (DC-DC) and LDO regulators
 - On-chip software controlled power management unit
 - On-chip 32 kHz LPO with optional external 32 kHz crystal oscillator support
- **Wi-Fi Coexistence**
 - Global Coexistence Interface (GCI) for Cypress Wi-Fi parts
 - Serial Enhanced Coexistence Interface (SECI)
- **Supported in ModusToolbox®**
- **OTA Firmware Update Support**
- **Grade-2 (–40 °C to +105 °C) Operation**
- **Package Types**
 - 48-pin WQFN
 - RoHS compliant

Applications

- **Automotive**
 - Car Access and Car Sharing
 - Keyless Entry
 - Passive Entry and Passive Start (PEPS)
 - Remote Parking
 - Wireless Diagnostics (OBD)
 - Sensors
 - Cable Replacement
- **Industrial**
 - Access Control
 - Asset Tracking
 - Factory Automation
 - Logistics Management
 - Sensors

1. Bluetooth Baseband Core

The Bluetooth Baseband Core (BBC) implements all of the time-critical functions required for high-performance Bluetooth operation. The BBC manages the buffering, segmentation, and routing of data for all ACL, SCO, eSCO, LE, and 2 Mbps LE connections. It prioritizes and schedules all RX/TX activities including adv, paging, scanning, and servicing of connections. In addition to these functions, it independently handles the host controller interface (HCI) including all commands, events, and data flowing over HCI. The core also handles symbol timing, forward error correction (FEC), header error control (HEC), cyclic redundancy check (CRC), authentication, data encryption/decryption, and data whitening/dewhitening.

Table 1 lists key Bluetooth features supported by the CYW89820.

1.1 BQB and Regulatory Testing Support

The CYW89820 fully supports Bluetooth Test Mode as described in Part I:1 of the Specification of the Bluetooth System v3.0. This includes the transmitter tests, normal and delayed loop back tests, and reduced hopping sequence.

In addition to the standard Bluetooth Test Mode, the CYW89820 also supports enhanced testing features to simplify RF debugging and qualification. These features include:

- Fixed frequency carrier wave (unmodulated) transmission
 - Simplifies some type-approval measurements (Japan)
 - Aids in transmitter performance analysis
- Fixed frequency constant receiver mode
 - Receiver output directed to I/O pin
 - Allows for direct BER measurements using standard RF test equipment
 - Facilitates spurious emissions testing for receive mode
- Fixed frequency constant transmission
 - 8-bit fixed pattern or PRBS-9
 - Enables modulated signal measurements with standard RF test equipment

1.2 Wi-Fi Coexistence Support

The CYW89820 includes support for:

- Global Coexistence Interface for use with Cypress Wi-Fi parts
- Serial Enhanced Coexistence Interface (SECI) for use with SECI compatible Wi-Fi parts

2. Microprocessor Unit

The CYW89820 includes a Cortex M4 processor with 1 MB of program ROM, 160 KB of data RAM, 16 KB of patch RAM, and 256 KB of flash. The CM4 has a maximum speed of 96 MHz. The 256 KB of flash is supported by an 8 KB cache allowing direct code execution from flash at near maximum speed and low power consumption.

The CM4 runs all the Bluetooth layers as well as application code. The ROM includes LMAC, HCI, L2CAP, GATT, as well as other stack layers freeing up most of the flash for application usage.

A standard serial wire debug (SWD) interface provides debugging support. Refer to the [Firmware](#) section for details on the architecture and layers that are included in the ROM.

2.1 Main Crystal Oscillator

The CYW89820 uses a 24 MHz crystal oscillator (XTAL).

The XTAL must have an accuracy of ± 20 ppm as defined by the Bluetooth specification. Two external load capacitors are required to work with the crystal oscillator. The selection of the load capacitors is XTAL-dependent (see [Figure 1](#)).

2.2 32 kHz Crystal Oscillator

The CYW89820 includes a 32 kHz oscillator to provide accurate timing during low power operations. Figure 2 shows the 32 kHz XTAL oscillator with external components and Table 3 lists the oscillator's characteristics. This oscillator can be operated with a 32 kHz or 32.768 kHz crystal oscillator or be driven with a clock input at similar frequency. The XTAL must have an accuracy of ± 250 ppm or better per the Bluetooth spec over temperature and including aging. The default component values are: $R1 = 10\text{ M}\Omega$ and $C1 = C2 = \sim 6\text{ pF}$. The values of $C1$ and $C2$ are used to fine-tune the oscillator.

2.3 Low-Frequency Clock Sources

The 32-kHz low-frequency clock (LPO_32K on the following figure) can be obtained from multiple sources. There are two internal low-power oscillators (LPOs), called the LP-LPO and HP-LPO, as well as external crystal connections (OSC32K). The firmware determines the clock source to use among the available LPOs depending on the accuracy and power requirements. The preferred source is the external LPO (OSC32K) because it has good accuracy with the lowest current consumption. Internal LP-LPO has low current consumption and low accuracy whereas HP-LPO has higher accuracy and higher current consumption. The firmware assumes the external LPO has less than 250 PPM error with little or no jitter.

Figure 3. Simplified Clock Source

2.4 Power Modes

The CYW89820 supports the following HW power modes:

- **Active Mode:** Normal operating mode in which all peripherals are available and CPU is active
- **Idle Mode - CPU is paused:** In this mode, the CPU is in "Wait for Interrupt" (WFI) and the HCLK, which is the high frequency clock derived from the main crystal oscillator, is running at a lower clock speed. Other clocks are active and the state of the entire chip is retained.
- **Sleep Mode:** All systems clocks idle except for the LPO. The chip can wake up either after a programmed period of time has expired or if an external event is received via one of the GPIOs. In this mode, CPU is in WFI and the HCLK is not running. The PMU determines if the other clocks can be turned off and does accordingly. State of the entire chip is retained, the internal LDOs run at a lower voltage (voltage is managed by the PMU), and SRAM is retained.
- **PDS (Power Down Sleep) Mode:** Radio powered down and digital core mostly powered down except for RAM, registers, and some core logic. CYW89820 can wake up either after a programmed period of time has expired or if an external event is received via one of the GPIOs.
- **ePDS (extended PDS) Mode:** This is an extension of the PDS Mode. In this mode, only the main RAM and ePDS control circuitry retains power. As in other modes, the CYW89820 can wake up either after a programmed period or upon receiving an external event.
- **HID-OFF (Deep Sleep) Mode:** Core, radio, and regulators powered down. Only the LHL IO domain is powered. In this mode, the CYW89820 can be woken up either by an event on one of the GPIOs or after a certain amount of time has expired. After wakeup, the part will go through full FW initialization although it will retain enough information to determine that it came out of HID-OFF and the event that caused the wake up. LPO and RTC are turned off in this mode. Either an internal LPO or an external input would provide a measure of time.

Transition between power modes is handled by the on-chip firmware with host/application involvement. In general ePDS is the most power efficient mode for most active use cases. HID-OFF generally works for non-connectable beacon type use cases with long advertisement intervals. Refer to the [Firmware](#) section for more details.

2.5 Watchdog

CYW89820 includes an onboard watchdog with a period of approx. 4 seconds. The watchdog timer generates an interrupt to the FW after 2 seconds of inactivity and resets the parts after 4 seconds.

2.6 Lockout Functionality

The CYW89820 power up with JTAG and SWD access to flash and RAM is disabled. After reset, FW checks OCF for the presence of a security lockout field. If present, FW leaves JTAG and SWD Flash and RAM access disabled and also blocks any HCI commands from reading the raw contents of the RAM or Flash.

The security field can be programmed in the factory after all programming and testing has been done. Refer to the [ModusToolbox](#) documentation for details on how to enable this feature. This provides an effective way of protecting against any tampering, dumping, probing or reverse engineering of OCF resident user application. The only FW upgrade path in this scenario is the secure OTA update.

2.7 True Random Number Generator

The CYW89820 includes a hardware TRNG. Applications can access the random number generator via the firmware driver. Refer to the [ModusToolbox](#) documentation for details.

3. Power On and External Reset

Figure 4 shows power on and reset timing of the CYW89820. After VBAT is applied and reset is inactive, the internal buck turns on, followed by the RF and Digital LDOs. Once the LDO outputs have stabilized, the PMU allows the digital core to come out of reset. As shown in the figure, external reset can be applied at any time subsequent to power up.

Figure 4. Reset Timing

4. Power Management Unit

Figure 5 shows the CYW89820 power management unit (PMU) block diagram. The CYW89820 includes an integrated buck regulator, a digital LDO for the digital core, and an RF LDO for the Radio. The PMU also includes a brownout detector which places the part in shutdown when input voltage is below a certain threshold.

Figure 5. Power Management Unit

5. Power Configurations

CYW89820 supports three power configurations as described in the following table.

Configuration	Description
VBAT and VDDIO	VBAT and VDDIO are supplied externally and are used to generate all other supplies on the device. Reset may be left floating as it has an internal pull-up, may be connected to an external RC, or may be driven externally.
External Supplies	PMU is disabled and on-chip regulators are not used. All supplies are provided externally. Reset is driven from the outside.
LDOs and VDDIO	On-chip LDOs are used to generate internal supplies but the on-chip buck is not used. Reset is driven externally.

5.1 Configuration 1 - VBAT and VDDIO

In this configuration the device is provided with two supplies (which can also be tied together). RST_N is either left floating and relies on the internal pull-up to VDDIO to bring the device out of reset or tied to an external RC, or driven externally. All other required supplies are generated on-chip (see the following figure). Note that VDDIO must be supplied at the same time or before VBAT is supplied.

The device may require an external reset when any supply voltages drop below 1V. POR operation not guaranteed below 1V.

5.2 Configuration 2 - External Supplies

In this configuration the internal regulators are not used and VBAT is not supplied. VDDIO is supplied along with externally generated core and radio supplies. This is shown in the following figure.

Note that VDDIO must be provided simultaneously or before the rest of the supplies and the device must be held in reset until all supplies are within normal operating ranges.

The device may require a reset if any supply goes outside the normal operating range.

5.3 Configuration 3 - LDOs and VDDIO

In this configuration the internal buck regulator is not used. Instead, power is supplied to the internal LDOs which are responsible for supplying the rest of the device.

Note that VDDIO must be provided simultaneously or before the rest of the supplies and the device must be held in reset until all supplies are within normal operating ranges. The internal LDOs have a small turn-on time (specified later in the datasheet) which should be accounted for before releasing reset.

The device may require a reset if any supply goes outside the normal operating range.

6. Integrated Radio Transceiver

The CYW89820 has an integrated radio transceiver that has been designed to provide low power operation in the globally available 2.4 GHz unlicensed ISM band. It is fully compliant with Bluetooth Radio Specification 5.0 and meets or exceeds the requirements to provide the highest communication link quality of service.

6.1 Transmitter Path

The CYW89820 features a fully integrated transmitter. The baseband transmit data is GFSK modulated in the 2.4 GHz ISM band.

Digital Modulator

The digital modulator performs the data modulation and filtering required for the GFSK signal. The fully digital modulator minimizes any frequency drift or anomalies in the modulation characteristics of the transmitted signal.

Power Amplifier

The CYW89820 has an integrated power amplifier (PA) that can transmit up to +10.5 dBm for class 1 operation.

6.2 Receiver Path

The receiver path uses a low IF scheme to down-convert the received signal for demodulation in the digital demodulator and bit synchronizer. The receiver path provides a high degree of linearity, and an extended dynamic range to ensure reliable operation in the noisy 2.4 GHz ISM band. The front-end topology, which has built-in out-of-band attenuation, enables the CYW89820 to be used in most applications without off-chip filtering.

Digital Demodulator and Bit Synchronizer

The digital demodulator and bit synchronizer take the low-IF received signal and perform an optimal frequency tracking and bit synchronization algorithm.

Receiver Signal Strength Indicator

The radio portion of the CYW89820 provides a receiver signal strength indicator (RSSI) to the baseband. This enables the controller to take part in a Bluetooth power-controlled link by providing a metric of its own receiver signal strength to determine whether the transmitter should increase or decrease its output power.

6.3 Local Oscillator

The local oscillator (LO) provides fast frequency hopping (1600 hops/second) across the band. The CYW89820 uses an internal loop filter.

7. Peripherals

7.1 I²C Compatible Master

The CYW89820 provides a 2-pin I²C compatible master interface to communicate with I²C compatible peripherals. The I²C compatible master supports the following clock speeds:

- 100 kHz
- 400 kHz
- 800 kHz (Not a standard I²C-compatible speed.)
- 1 MHz (Compatibility with high-speed I²C-compatible devices is not guaranteed.)

The I²C compatible master is capable for doing read, write, write followed by read, and read followed by write operations where read/write can be up to 64 bytes.

SCL and SDA lines can be routed to any of the P1-P37 GPIOs allowing for flexible system configuration. When used as SCL/SDA the GPIOs go into open drain mode and require an external pull-up for proper operation. BSC does not support multimaster capability or flexible wait-state insertion by either master or slave devices.

7.2 Serial Peripheral Interface

The CYW89820 has two independent SPI interfaces. Both interfaces support single, dual, and Quad Mode SPI operations. Either interface can be a master or a slave. SPI1 has 1040-byte transmit and receive buffers (shared with UART) and SPI2 has 256-byte dedicated transmit and receive buffers. To support more flexibility for user applications, the CYW89820 has optional I/O ports that can be configured individually and separately for each functional pin.

SPI IO voltage depends on VDDO.

7.3 HCI UART Interface

The CYW89820 includes a UART interface for factory programming as well as when operating as a Bluetooth HCI device in a system with an external host. The UART physical interface is a standard, 4-wire interface (RX, TX, RTS, and CTS) with adjustable baud rates from 115200 bps to 3 Mbps. Typical rates are 115200, 921600, 1500000, and 3,000,000 bps although intermediate speeds are also available. Support for changing the baud rate during normal HCI UART operation is included through a vendor-specific command. The CYW89820 UART operates correctly with the host UART as long as the combined baud rate error of the two devices is within $\pm 5\%$. The UART interface CYW89820 has a 1040-byte receive FIFO and a 1040-byte transmit FIFO to support enhanced data rates. The interface supports the Bluetooth UART HCI (H4) specification. The default baud rate for H4 is 115.2 kbaud.

In HCI Mode, the CYW89820 can wake up the host as needed or allow the host to sleep via the HOST_WAKE signal. The HOST_WAKE signal can be enabled via a vendor specific command.

The FW UART driver allows applications to select different baud rates.

7.4 Peripheral UART Interface

The CYW89820 has a second UART that may be used to interface to peripherals. Functionally, the peripheral UART is the same as the HCI UART except for 256 byte TX/RX FIFOs. The peripheral UART is accessed through the I/O ports, which can be configured individually and separately for each functional pin. The CYW89820 can map the peripheral UART to any LHL GPIO.

7.5 GPIO Ports

The CYW89820 has 17 general purpose IOs labeled P1-P37. All GPIOs support the following:

- programmable pull-up/down of approx 45 k Ω
- input disable, allowing pins to be left floating or analog signals connected without risk of leakage
- source/sink 8 mA at 3.3V and 4 mA at 1.8V
- P26/P27/P28/P29 sink/source 16 mA at 3.3V and 8 mA at 1.8V

Most peripheral functions can be assigned to any GPIO. For details, see [Table 5](#) and [Table 6](#).

7.6 ADC

The CYW89820 includes a $\Sigma\Delta$ ADC designed for audio and DC measurements. The ADC can measure the voltage on 14 GPIO (P1, P9-14, P17-19, P28, P29, P32, P37). When used for analog inputs, the GPIOs must be placed in digital input disable mode to disconnect the digital circuit from the pin and avoid leakage. The internal bandgap reference has $\pm 5\%$ accuracy without calibration. Calibration and digital correction schemes can be applied to reduce ADC absolute error and improve measurement accuracy in Direct Current (DC) Mode.

The application can access the ADC through the ADC driver included in the firmware.

7.7 PWM

The CYW89820 has four internal PWMs, labeled PWM0-3.

- Each of the six PWM channels contains the following registers:
 - 16-bit initial value register (read/write)
 - 16-bit toggle register (read/write)
 - 16-bit PWM counter value register (read)
- PWM configuration register is shared among PWM0-3 (read/write). This 18-bit register is used:
 - To enable/disable each PWM channel
 - To select the clock of each PWM channel
 - To invert the output of each PWM channel. The application can access the PWM module through the FW driver.

Figure 6 shows the structure of one PWM channel.

Figure 6. PWM Block Diagram

7.8 PDM Microphone

The CYW89820 accepts a $\Sigma\Delta$ -based one-bit pulse density modulation (PDM) input stream and outputs filtered samples at either 8 kHz or 16 kHz sampling rates. The PDM signal derives from an external kit that can process analog microphone signals and generate digital signals. The PDM inputs share the filter path with the aux ADC. Two types of data rates can be supported:

- 8 kHz
- 16 kHz

The external digital microphone takes in a 2.4 MHz clock generated by the CYW89820 and outputs a PDM signal which is registered by the PDM interface with either the rising or falling edge of the 2.4 MHz clock selectable through a programmable control bit. The design can accommodate two simultaneous PDM input channels, so stereo voice is possible.

7.9 I²S Interface

The CYW89820 supports a single I²S digital audio port with both master and slave modes. The I²S signals are:

- I²S Clock: I²S SCK
- I²S Word Select: I²S WS
- I²S Data Out: I²S DO
- I²S Data In: I²S DI

I²S SCK and I²S WS become outputs in master mode and inputs in slave mode, while I²S DO always stays as an output. The channel word length is 16 bits and the data is justified so that the MSN of the left-channel data is aligned with the MSB of the I²S bus, per I²S Specifications. The MSB of each data word is transmitted one bit clock cycle after the I²S WS transition, synchronous with the falling edge of bit clock. Left Channel data is transmitted when I²S WS is low, and right-channel data is transmitted when I²S WS is high. Data bits sent by the CYW89820 are synchronized with the falling edge of I²S SCK and should be sampled by the receiver on the rising edge of the I²S SCK.

The clock rate in master mode as follows:

- 16 kHz $\times$ 16 bits per frame = 256 kHz

The master clock is generated from the reference clock using an N/M clock divider. In the slave mode, any clock rate is supported up to a maximum of 3.072 MHz.

7.10 PCM Interface

The CYW89820 includes a PCM interface that can connect to linear PCM codec devices in master or slave mode. In master mode, the CYW89820 generates the PCM_CLK and PCM_SYNC signals. In slave mode, these signals are provided by another master on the PCM interface and are inputs to the CYW89820. The configuration of the PCM interface may be adjusted by the host through the use of vendor-specific HCI commands.

Note PCM interface shares HW with the I2S interface and only one can be used at any time. Only audio source (other than SCO) use cases are supported on CYW89820.

7.10.1 Slot Mapping

The CYW89820 supports up to three simultaneous full-duplex channels through the PCM Interface. These three channels are time-multiplexed onto the single PCM interface by using a time-slotting scheme where the 8 kHz or 16 kHz audio sample interval is divided into as many as 16 slots. The number of slots is dependent on the selected interface rate (128 kHz, 512 kHz, or 1024 kHz). The corresponding number of slots for these interface rate is 1, 2, 4, 8, and 16, respectively. Transmit and receive PCM data from an SCO channel is always mapped to the same slot. The PCM data output driver tristates its output on unused slots to allow other devices to share the same PCM interface signals. The data output driver tristates its output after the falling edge of the PCM clock during the last bit of the slot.

7.10.2 Frame Synchronization

The CYW89820 supports both short- and long-frame synchronization in both master and slave modes. In short frame synchronization mode, the frame synchronization signal is an active-high pulse at the audio frame rate that is a single-bit period in width and is synchronized to the rising edge of the bit clock. The PCGM slave looks for a high on the falling edge of the bit clock and expects the first bit of the first slot to start at the next rising edge of the clock. In long-frame synchronization mode, the frame synchronization signal is again an active-high pulse at the audio frame rate; however, the duration is three bit periods and the pulse starts coincident with the first bit of the first slot.

7.10.3 Data Formatting

The CYW89820 may be configured to generate and accept several different data formats. For conventional narrow band speech mode, the CYW89820 uses 13 of the 16 bits in each PCM frame. The location and order of these 13 bits can be configured to support various data formats on the PCM interface. The remaining three bits are ignored on the input and may be filled with 0s, 1s, a sign bit, or a programmed value on the output. The default format is 13-bit 2's complement data, left justified, and clocked MSB first.

8. Firmware

The CYW89820 ROM firmware runs on a real time operating system and handles the programming and configuration of all on-chip hardware functions as well as the Bluetooth/LE baseband, LMAC, HCI, GATT, ATT, L2CAP, and SDP layers. The ROM also includes drivers for on-chip peripherals as well as handling on-chip power management functions including transitions between different power modes. The ROM also supports OTA firmware update and acts as a root of trust.

The CYW89820 is fully supported by the Cypress ModusToolbox. ModusToolbox releases provide latest ROM patches, drivers, and sample applications allowing customized applications using the CYW89820 to be built quickly and efficiently.

Refer to the [ModusToolbox](#) documentation for details on the firmware architecture and how to write applications/profiles using the CYW89820.

9. Pin Assignments and GPIOs

This section addresses 48-pin WQFN pin assignment and general purpose IOs (GPIOs) for the CYW89820 device.

Table 4. 48-pin WQFN Pin Assignment

Pin Name	Pin Number WQFN-48	I/O	Power Domain	Description

11. Specifications

11.1 Electrical Characteristics

Caution! The absolute maximum ratings in Table 7 indicate levels where permanent damage to the device can occur, even if these limits are exceeded for only a brief duration. Functional operation is not guaranteed under these conditions. Operation at absolute maximum conditions for extended periods can adversely affect long-term reliability of the device.

Notes

9. The receiver sensitivity is measured at BER of 0.1% on the device interface with dirty TX Off.

10. Desired signal is 10 dB above the reference sensitivity level (defined as –70 dBm).

11. Desired signal is 3 dB above the reference sensitivity level (defined as –70 dBm).

12. Desired signal is –64 dBm Bluetooth-modulated signal, interferer 1 is –39 dBm sine wave at frequency f1, interferer 2 is –39 dBm Bluetooth-modulated signal at frequency f2, $f_0 = 2 * f_1 - f_2$, and $|f_2 - f_1| = n * 1 \text{ MHz}$, where $n = 3, 4, \text{ or } 5$. For the typical case, $n = 4$.

Master Mode: Clock generated by transmitter or receiver									
HIGH t _{HC}	0.35T _{tr}	—	—	—	0.35T _{tr}	—	—	—	[19]
LOWt _{LC}	0.35T _{tr}	—	—	—	0.35T _{tr}	—	—	—	[19]
Slave Mode: Clock accepted by transmitter or receiver									
HIGH t _{HC}	—	0.35T _{tr}	—	—	—	0.35T _{tr}	—	—	[18]
LOW t _{LC}	—	0.35T _{tr}	—	—	—	0.35T _{tr}	—	—	[18]
Rise time t _{RC}	—	—	0.15T _{tr}	—	—	—		—	[19]
Transmitter									
Delay t _{dtr}	—	—	—	0.8T	—	—	—	—	[20]
Hold time t _{htr}	0	—	—	—	—	—	—	—	[19]
Receiver									
Setup time t _{sr}	—	—	—	—	0.2T _{tr}	—	—	—	[21]
Hold time t _{hr}	—	—	—	—	0.2T _{tr}	—	—	—	[21]

Notes

18. The system clock period T must be greater than T_{tr} and T_r because both the transmitter and receiver have to be able to handle the data transfer rate.
19. At all data rates in master mode, the transmitter or receiver generates a clock signal with a fixed mark/space ratio. For this reason, t_{HC} and t_{LC} are specified with respect to T.
20. In slave mode, the transmitter and receiver need a clock signal with minimum HIGH and LOW periods so that they can detect the signal. So long as the minimum periods are greater than $0.35T_r$, any clock that meets the requirements can be used.
21. Because the delay (t_{dtr}) and the maximum transmitter speed (defined by T_{tr}) are related, a fast transmitter driven by a slow clock edge can result in t_{dtr} not exceeding t_{RC} which means t_{htr} becomes zero or negative. Therefore, the transmitter has to guarantee that t_{htr} is greater than or equal to zero, so long as the clock rise-time t_{RC} is not more than t_{RCmax} , where t_{RCmax} is not less than $0.15T_{tr}$.
22. To allow data to be clocked out on a falling edge, the delay is specified with respect to the rising edge of the clock signal and T, always giving the receiver sufficient setup time.
23. The data setup and hold time must not be less than the specified receiver setup and hold time.
