LTC4303

Hot Swappable 2-Wire Bus Buffer with Stuck Bus Recovery

FEATURES

- Automatic Disconnect of SDA/SCL Lines when Bus is Stuck Low for ≥ 30ms
- Recovers Stuck Busses with Automatic Clocking*
- Bidirectional Buffer* for SDA and SCL Lines Increases Fanout
- Prevents SDA and SCL Corruption During Live Board Insertion and Removal from Backplane
- Pin Compatible with LTC4300A-1
- ±15kV Human Body Model ESD Protection
- Isolates Input SDA and SCL Lines from Output
- Compatible with I²C™, I²C Fast-Mode and SMBus Standards (Up to 400kHz Operation)
- READY Open Drain Output
- 1V Precharge on All SDA and SCL Lines
- High Impedance SDA, SCL Pins for VCC = 0V
- ENABLE Gates Connection from Input to Output
- MSOP 8-Pin and DFN (3mm × 3mm) Packages

APPLICATIONS

- Hot Board Insertion
- Servers
- Capacitance Buffer/Bus Extender
- RAID Systems

DESCRIPTION

The LTC®4303 hot swappable 2-wire Bus Buffer allows I/O card insertion into a live backplane without corruption of the data and clock busses. When a connection is made, the LTC4303 provides bidirectional buffering, keeping the backplane and card capacitances isolated. If SDAOUT or SCLOUT is low for ≥ 30ms (typ), the LTC4303 automatically breaks the data and clock bus connection. At this time the LTC4303 automatically generates up to 16 clock pulses on SCLOUT in an attempt to free the bus. A connection will be enabled automatically when the bus becomes free.

Rise-time accelerator circuitry allows the use of larger pull-up resistance while still meeting rise-time requirements. During insertion, the SDA and SCL lines are precharged to 1V to minimize bus disturbances. When driven high, ENABLE allows the LTC4303 to connect after a stop bit or bus idle occurs. Driving ENABLE low breaks the connection between SDAIN and SDAOUT, SCLIN and SCLOUT. READY is an open drain output that indicates when the backplane and card sides are connected together.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into pins are positive; all voltages are referenced to GND unless otherwise specified.

**Note 3:** Pulsed less than 5µs.

**Note 4:** The connection circuitry always regulates the output to a higher voltage than its input. The magnitude of this offset voltage as a function of the pull-up resistor and $V_{CC}$ voltage is shown in the Typical Performance Characteristics section.

**Note 5:** $I_{FULLUPAC}$ varies with temperature and $V_{CC}$ voltage, as shown in the Typical Performance Characteristics section.

**Note 6:** Guaranteed by design, not tested in production.

**Note 7:** $I_{CC}$ test performed with connection circuitry active.
TYPICAL PERFORMANCE CHARACTERISTICS  \( T_A = 25^\circ C \) unless otherwise indicated.
**PIN FUNCTIONS**

ENABLE (Pin 1): Connection Enable. This is a digital threshold input pin. For normal operation ENABLE is high. Driving ENABLE below 0.8V isolates SDAIN from SDAOUT, SCLIN from SCLOUT, asserts READY low and disables automatic clocking. A rising edge on ENABLE after a fault has occurred unconditionally forces a connection between SDAIN, SDAOUT and SCLIN, SCLOUT.

SCLOUT (Pin 2): Serial Clock Output. Connect this pin to the SCL bus on the card.

SCLIN (Pin 3): Serial Clock Input. Connect this pin to SCL on the bus backplane.

GND (Pin 4): Device Ground. Connect this pin to a ground plane for best results.

READY (Pin 5): Connection Status Flag. READY provides a digital flag which indicates the status of the connection circuitry described in the “Connection Circuitry” section. Connect a resistor of 10k to VCC to provide the pull-up.

SDAIN (Pin 6): Serial Data Input. Connect this pin to the SDA bus on the backplane.

SDAOUT (Pin 7): Serial Data Output. Connect this pin to the SDA bus on the card.

VCC (Pin 8): Supply Voltage Input. Place a bypass capacitor of at least 0.01µF close to VCC for best results.

Exposed Pad (Pin 9, DFN Only): Exposed pad may be left open or connected to the ground plane.

**BLOCK DIAGRAM**

LTC4303 2-Wire Bus Buffer with Stuck Bus Protection

Downloaded from Arrow.com.
When the LTC4303 first receives power on its V CC pin, either during power up or live insertion, it starts in an under voltage lockout (UVLO) state, ignoring any activity on the SDA or SCL pins until V CC rises above 2.5V (typical).

During this time, the precharge circuitry is active and forces 1V through 200k nominal resistors to the SDA and SCL pins. Because the I/O card is being plugged into a live backplane, the voltage on the backplane SDA and SCL busses may be anywhere between 0V and V CC. Precharging the SCL and SDA pins to 1V minimizes the worst-case voltage differential these pins will see at the moment of connection, therefore minimizing the amount of disturbance caused by the I/O card.

Once the LTC4303 comes out of UVLO, it assumes that SDAIN and SCLIN have been inserted into a live system and that SDAOUT and SCLOUT are being powered up at the same time as itself. Therefore, it looks for either a stop bit or bus idle condition on the input side to indicate the completion of a data transaction. When either one occurs, the part also verifies that both the SDAOUT and SCLOUT voltages are high. When all of these conditions are met, the input-to-output connection circuitry is activated, joining the SDA and SCL busses on the I/O card with those on the backplane and READY goes high.

**Connection Circuitry**

Once the connection circuitry is activated, the functionality of the SDAIN and SDAOUT pins is identical. A low forced on either pin at any time results in both pin voltages being low. **For proper operation, logic low input voltages should be no higher than 0.4V with respect to the ground pin voltage of the LTC4303.** SDAIN and SDAOUT enter a logic high state only when all devices on both SDAIN and SDAOUT release high. The same is true for SCLIN and SCLOUT. This important feature ensures that clock stretching, clock synchronization, arbitration and the acknowledge protocol always work, regardless of how the devices in the system are tied to the LTC4303.

Another key feature of the connection circuitry is that it provides bidirectional buffering, keeping the backplane and card capacitances isolated. Because of this isolation, the waveforms on the backplane busses look slightly different than the corresponding card bus waveforms, as described here.

### Input to Output Offset Voltage

When a logic low voltage, $V_{LOW1}$, is driven on any of the LTC4303’s data or clock pins, the LTC4303 regulates the voltage on the opposite side of the part (call it $V_{LOW2}$) to a slightly higher voltage, as directed by the following equation:

$$V_{LOW2} = V_{LOW1} + 75mV + (V_{CC}/R) \times 20\Omega \text{ (typical)}$$

where $R$ is the bus pull-up resistance in ohms. For example, if a device is forcing SDAOUT to 10mV where $V_{CC} = 3.3V$ and the pull-up resistor $R$ on SDAIN is 10k, then the voltage on SDAIN = 10mV + 75mV + (3.3/10000) \times 20 = 91.6mV (typical). See the Typical Performance Characteristics section for curves showing the offset voltage as a function of $V_{CC}$ and $R$.

### Bus Stuck Low Time-Out

When SDAOUT or SCLOUT is low, an internal timer starts. The timer is only reset when SDAOUT and SCLOUT are both high. If they do not go high within 30ms (typical), the connection between SDAIN and SDAOUT, and SCLIN and SCLOUT is broken. After a delay of at least 40µs the LTC4303 automatically generates up to 16 clock pulses at 8.5kHz (typical) on SCLOUT in an attempt to unstick the bus. When SDAOUT and SCLOUT go high, reconnection occurs when the conditions described in the “Start-Up” section above are satisfied.

When powering up into a bus stuck low condition, the connection circuitry joining the SDA and SCL busses on the I/O card with those on the backplane is not activated. 30ms after UVLO, automatic clocking takes place as described above.

### Propagation Delays

During a rising edge, the rise-time on each side is determined by the bus pull-up resistor and the equivalent capacitance on the line. If the pull-up resistors are the same, a difference in rise-time occurs which is directly proportional to the difference in capacitance between...
The two sides. This effect is displayed in Figure 1 for a
$V_{CC} = 3.3V$ and a 10k pull-up resistor on each side (50pF
on one side and 150pF on the other). Since the output side
has less capacitance than the input, it rises faster and the
effective $t_{PLH}$ is negative.

There is a propagation delay, $t_{PHL}$, through the connec-
tion circuitry for falling waveforms. Figure 2 shows the
falling edge waveforms. An external driver pulls down
the voltage on the side with 50pF capacitance; LTC4303
pulls down the voltage on the opposite side with a delay
of 80ns. This delay is always positive and is a function of
supply voltage, temperature and the pull-up resistors and
equivalent bus capacitances on both sides of the bus. The
Typical Performance Characteristics section shows $t_{PHL}$
as a function of temperature and voltage for 10k pull-up
resistors and 100pF equivalent capacitance on both sides
of the part. Larger output capacitances translate to longer
delays. Users must quantify the difference in propagation
times for a rising edge versus a falling edge in their systems
and adjust setup and hold times accordingly.

**READY Digital Output**

The READY pin provides a digital flag which indicates the
status of the connection circuitry described previously in
the “Connection Circuitry” section. READY is high when
the connection circuitry is active, and pulls low when
there is not a valid connection. The pin is driven by an
open drain pull-down capable of sinking 3mA while hold-
ing 0.4V on the pin. Connect a resistor of 10k to $V_{CC}$
to provide the pull-up.

**ENABLE**

When the ENABLE pin is driven below 0.8V with respect
to the LTC4303’s ground, the backplane side is discon-
ected from the card side, and the READY pin is internally
pulled low. When the pin is driven above 2V, the part waits
for data transactions on the IN side to be complete and
for the OUT side to be high (as described in the Start-Up
section) before connecting the two sides. At this time the
internal pull-down on READY releases. When ENABLE is
low, automatic clocking is disabled.

A rising edge on ENABLE after a stuck bus condition has
occurred forces a connection between SDAIN, SDAOUT
and SCLIN, SCLOUT even if bus idle conditions are not
met. At this time the internal 30ms timer is reset but not
disabled.

**Rise Time Accelerators**

Once connection has been established, rise time accelerator
circuits on all four SDA and SCL pins are activated. These
allow the use of larger pull-up resistors, reducing power
consumption, or bus capacitance beyond that specified
in I²C, while still meeting system rise time requirements.
During positive bus transitions, the LTC4303 switches in
3.5mA (typical) of current to quickly slew the SDA and
SCL lines once their DC voltages exceed 0.8V. Choose a
pull-up resistor so that the bus will rise on its own at a
rate of at least 0.8V/µs to guarantee activation of the ac-
celerators. Rise time accelerators turn off when SDA and
SCL lines are approximately 1V below $V_{CC}$. The rise time
accelerators are automatically disabled during automatic
clocking.
**Applications Information**

**Resistor Pull-Up Selection**

The system pull-up resistors must be strong enough to provide a positive slew rate of 0.8V/µs on the SDA and SCL pins, in order to activate the rise time accelerators during rising edges. Choose maximum resistor value \( R_{\text{PULL-UP(MAX)}} \) using the formula:

\[
R_{\text{PULL-UP(MAX)}}(\text{k}\Omega) = \frac{(V_{\text{BUS(MIN)}} - 0.8V) \cdot 1250[\text{ns/V}]}{C_{\text{BUS}}[\text{pF}]}
\]

For example, assume \( V_{\text{BUS}} = V_{\text{CC}} = 3.3V \), and assuming ±10% supply tolerance, \( V_{\text{BUS(MIN)}} = 2.97V \). With \( C_{\text{BUS}} = 100\text{pF} \), \( R_{\text{PULL-UP MAX}} = 27.1k \). Therefore a smaller pull-up resistor than 27.1k must be used, so 10k works fine.

**Live Insertion and Capacitance Buffering Application**

Figures 3 through 6 illustrate applications of the LTC4303 that take advantage of both its Hot Swap™ controlling and capacitance buffering features. In all of these applications, note that if the I/O cards were plugged directly into the backplane without the LTC4303 buffer, all of the backplane and card capacitances would add directly together, making rise- and fall-time requirements difficult to meet. Placing a LTC4303 on the edge of each card, however, isolates the card capacitance from the backplane. For a given I/O card, the LTC4303 drives the capacitance on the card side and the backplane must drive only the digital input capacitance of the LTC4303, which is less than 10pF.

In most applications the LTC4303 will be used with a staggered connector where \( V_{\text{CC}} \) and GND will be long pins. SDA and SCL are medium length pins to ensure that the \( V_{\text{CC}} \) and GND pins make contact first. This will allow the precharge circuitry to be activated on SDA and SCL before they make contact. ENABLE is a short pin that is pulled down when not connected. This is to ensure that the connection between the backplane and the cards data and clock busses is not enabled until the transients associated with live insertion have settled.

Figure 3 shows the LTC4303 in a CompactPCI™ configuration. Connect \( V_{\text{CC}} \) and ENABLE to the output of one of the CompactPCI power supply Hot Swap circuits. Use a pull-up resistor to ENABLE for a card side enable/disable. \( V_{\text{CC}} \) is monitored by a filtered UVLO circuit. With the \( V_{\text{CC}} \) voltage powering up after all the other pins have established connection, the UVLO circuit ensures that the backplane and the card data and clock busses are not connected until the transients associated with live insertion have settled. Owing to their small capacitance, the SDAIN and SCLIN pins cause minimal disturbance on the backplane busses when they make contact with the connector.

Figure 4 shows the LTC4303 in a PCI application where all of the pins have the same length. In this case, a RC filter circuit on the I/O card with a product of 10ms provides a filter to prevent the LTC4303 from becoming activated until the transients associated with live insertion have settled. Connect the capacitor between ENABLE and GND, and the resistor from \( V_{\text{CC}} \) to ENABLE.
