![ANALOG DEVICES]

Xstream™ 3.2 Gbps
Quad Buffer Mux/Demux

Data Sheet

AD8159

FEATURES

Port level 2:1 mux/1:2 demux
Each port consists of 4 lanes
Each lane runs from dc to 3.2 Gbps, independent of the other lanes
Compensates over 40 inches of FR4 at 3.2 Gbps through 2 levels of input equalization or 4 levels of output pre-emphasis
Accepts ac- or dc-coupled differential CML inputs
Low deterministic jitter, typically 20 ps p-p
Low random jitter, typically 1 ps rms
BER < 10^{-16}
On-chip termination
Reversible inputs and outputs on one port
Unicast or bicast on 1:2 demux function
Port level loopback capability
Single lane switching capability
3.3 V core supply
Flexible I/O supply down to 2.5 V
Low power, typically 1 W in basic configuration
100-lead TQFP_EP
−40°C to +85°C operating temperature range

APPLICATIONS

Low cost redundancy switch
SONET OC-48/SDH-16 and lower data rates
XAUI (10 gigabit Ethernet) over backplane
Gigabit Ethernet over backplane
Fibre Channel 1.06 Gbps and 2.125 Gbps over backplane
InfiniBand® over backplane
PCI Express (PCIe) over backplane

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

GENERAL DESCRIPTION

The AD8159[1] is an asynchronous, protocol agnostic, quad-lane 2:1 switch with 12 differential PECL-/CML-compatible inputs and 12 differential CML outputs. The operation of this product is optimized for NRZ signaling with data rates of up to 3.2 Gbps per lane. Each lane offers two levels of input equalization and four levels of output pre-emphasis.

The AD8159 consists of four multiplexers and four demultiplexers, one per lane. Each port is a four-lane link, and each lane runs up to a 3.2 Gbps data rate, independent of the other lanes. The lanes are switched independently using the four select pins, SEL[3:0]; each select pin controls one lane of the port. The AD8159 has low latency and very low lane-to-lane skew.

[1] Product covered by one or more patents: U.S. Patent No. 7,813,706.

The main application of the AD8159 is to support redundancy on both the backplane side and the line interface side of a serial link. The device has unicast and bicast capability; therefore, it can be configured to support either 1 + 1 or 1:1 redundancy.

The AD8159 supports reversing of the output and input pins on one of its ports, which helps to connect two ASICs with opposite pinouts.

The AD8159 is also used for testing high speed serial links by duplicating incoming data and sending it to the destination port and to the test equipment simultaneously.

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
V_{CC} to V_{EE}	3.7 V
V_{TTI}	V_{CC} + 0.6 V
V_{TTIO}	V_{CC} + 0.6 V
V_{TTO}	V_{CC} + 0.6 V
V_{TTOI}	V_{CC} + 0.6 V
Internal Power Dissipation	4.26 W
Differential Input Voltage	2.0 V
Logic Input Voltage	V_{EE} − 0.3 V < V_{IN} < V_{CC} + 0.6 V
Storage Temperature Range	−65°C to +125°C
Lead Temperature	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.
PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration

NC = NO CONNECT

NOTES
1. THE AD8159 TQFP HAS AN EXPOSED PADDLE (ePAD) ON THE UNDERSIDE OF THE PACKAGE WHICH AIDS IN HEAT DISSIPATION. THE ePAD MUST BE ELECTRICALLY CONNECTED TO THE V$_{EE}$ SUPPLY PLANE IN ORDER TO MEET THERMAL SPECIFICATIONS.

THEORY OF OPERATION

The AD8159 relays received data on the demultiplexer Input Port C to Output Port A and/or Output Port B, depending on the mode selected by the BICAST control pin. On the multiplexer side, the AD8159 relays received data on either Input Port A or Input Port B to the Output Port C, based on the SEL[3:0] pin states.

The AD8159 is configured by toggling control pins. On the demultiplexer side, when the device is configured in unicast mode, it sends the received data on Input Port C to Output Port A or Output Port B. When the device is configured in bicast mode, received data on Input Port C is sent to both Output Port A and Output Port B.

On the multiplexer side, only received data on Input Port A or Input Port B is sent to Output Port C, depending on the state of the SEL[3:0] pins. Table 4 summarizes port selection and configuration when loopback is disabled (LB_A = LB_B = LB_C = 0).

When the device is in unicast mode, the output lanes on either Port A or Port B are in an idle state. In the idle state, the output tail current is set to 0 mA, and the P and N sides of the lane are pulled up to the output termination voltage through the on-chip termination resistors.

Table 4. Port Selection and Configuration Table

| SELx	BICAST	OUT_A	OUT_B	OUT_C
0	0	IN_C	Idle	IN_A
0	1	IN_C	IN_C	IN_A
1	0	Idle	IN_C	IN_B
1	1	IN_C	IN_C	IN_B

INPUT EQUALIZATION (EQ) AND OUTPUT PRE-EMPHASIS (PE)

In backplane applications, the AD8159 needs to compensate for signal degradation over potentially long traces. The device supports two levels of input equalization, configured on a per-port basis. Table 5 summarizes the high frequency gain (EQ) for each control setting, as well as the typical length of backplane trace that can be compensated for each setting.

Table 5. Input Equalization Settings

EQ_x	EQ (dB)	Typical Backplane Length (Inches)
0	6	0 to 20
1	12	20 to 40+

The AD8159 also has four levels of output pre-emphasis, configured for each port. The pre-emphasis circuitry adds a controlled amount of overshoot to the output waveform to compensate for the loss in a backplane trace.

Table 6 summarizes the high frequency gain, amount of overshoot, and the typical backplane channel length (including two connectors) that can be compensated for using each setting. A typical backplane is made of FR4 material with 8 mil wide traces and 8 mil spacing, loosely coupled differential traces. Each backplane channel consists of two connectors. The total length of the channel includes 3 inches of traces on each card.

Table 6. Output Pre-Emphasis Settings

PE_x[1]	PE_x[0]	PE (dB)	Overshoot	Typical Backplane Length (Inches)
0	0	0	0%	0 to 10
0	1	1.9	15%	10 to 20
1	0	3.5	35%	20 to 30
1	1	4.9	60%	30 to 40+

LOOPBACK

The AD8159 also supports port level loopback, as is shown in
Figure 34. The loopback control pins override the lane select
(SEL[3:0]) and bicast control (BICAST) pins. Table 7 summarizes
the different loopback configurations.
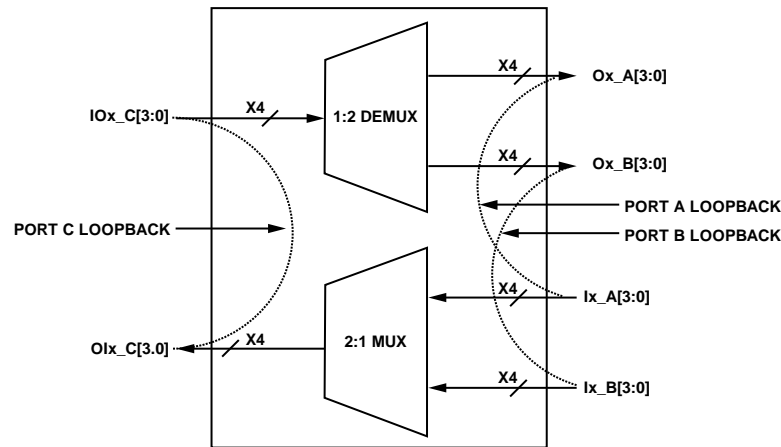

Figure 34. Port-Based Loopback Capability

Table 7. Loopback, Bicast, and Port Select Settings[1]

LB_A	LB_B	LB_C	SELx	BICAST	OUT_A	OUT_B	OUT_C

[1] Switching is done on a lane-by-lane basis, but input equalization, output pre-emphasis, and loopback are set for each port.
[2] Don't care.

PORT C REVERSE (CROSSOVER) CAPABILITY

Port C has a reversible I/O capability. The sense (input vs. output) of the Port C pins can be swapped by toggling the REVERSE_C control pin. This feature was added to facilitate the connection to different ASICs that may have the opposite pinouts.

Figure 35 illustrates the reversible I/O function of Port C, and Table 8 describes this function in a selection table that corresponds to a TQFP-100 package. Note that the reverse capability is supported only on Port C.

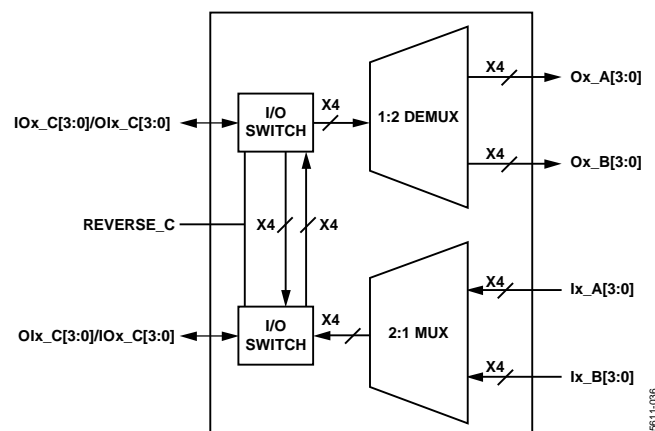

Figure 35. Port C Reverse I/O Capability

APPLICATIONS INFORMATION

The main application of the AD8159 is to support redundancy on both the backplane side and the line interface side of a serial link. Each port consists of four lanes to support standards such as XAUI. Figure 36 illustrates redundancy in an XAUI backplane system. Each line card is connected to two switch fabrics (primary and redundant). The device can be configured to support either 1 + 1 or 1:1 redundancy.

Another application for the AD8159 is test equipment for evaluating high speed serial I/Os running at data rates at or lower than 3.2 Gbps. Figure 37 illustrates the module redundancy of a line card application. Figure 38 illustrates a possible application of the AD8159 in a simple XAUI link tester.

Rev. C | Page 18 of 21

INTERFACING TO THE AD8159

TERMINATION STRUCTURES

To determine the best strategy for connecting to the high speed pins of the AD8159, the user must first be familiar with the on-chip termination structures. The AD8159 contains multiple types of these structures (see Figure 39, Figure 40, and Figure 41). Note that Port C has a slightly modified termination structure to support the bidirectional feature.
Figure 39. Simplified Input Circuit

*Figure 40. Simplified Output Circuit (Port A or Port B)*

Figure 41. Simplified Output Circuit (Port C)

For input and bidirectional ports, the termination structure consists of two 55 Ω resistors connected to a termination supply and an 1173 Ω resistor connected across the differential inputs, the latter being a result of the finite differential input impedance of the equalizer.

For output ports, there are two 50 Ω resistors connected to the termination supply. Note that the differential input resistance for both structures is the same, 100 Ω.

INPUT COMPLIANCE

The range of allowable input voltages is determined by the fundamental limitations of the active input circuitry. This range of signals is normally a function of the common-mode level of the input signal, the signal swing, and the supply voltage. For a given input signal swing, there is a range of common-mode voltages that keeps the high and low voltage excursions within acceptable limits. Similarly, for a given common-mode input voltage, there is a maximum acceptable input signal swing. There is also a minimum signal swing that the active input circuitry can resolve reliably.

Figure 22 and Figure 25 summarize the input voltage ranges for all ports. Note that the input range is different when comparing bidirectional ports to strictly input ports. This is a consequence of the additional circuitry required to support the bidirectional feature on Port C.

AC Coupling

One way to simplify the input circuit and make it compatible with a wide variety of driving devices is to use ac coupling. This has the effect of isolating the dc common-mode levels of the driver and the AD8159 input circuitry. AC coupling requires a capacitor in series with each single-ended input signal, as shown in Figure 42. This should be done in a manner that does not interfere with the high speed signal integrity of the PCB.
Figure 42. AC Coupling Input Signal of the AD8159

When ac coupling is used, the common-mode level at the input of the device is equal to V_{TTI}. The single-ended input signal swings above and below V_{TTI} equally. The user can then use Figure 22 and Figure 25 to determine the acceptable range of common-mode levels and signal swing levels that satisfy the input range of the AD8159.

If dc coupling is required, determining the input common-mode level is less straightforward because the configuration of the driver must also be considered. In most cases, the user sets V_{TTI} on the AD8159 to the same level as the driver output termination voltage, V_{TTOD}. This prevents a continuous dc current from flowing between the two supplies. As a practical matter, both devices can be terminated to the same physical supply.

Consider the following example: a driver dc-coupled to the input of the AD8159. The AD8159 input termination voltage (V_{TTI}) and the driver output termination voltage (V_{TTOD}) are both set to the same level; that is, $V_{TTI} = V_{TTOD} = 3.3$ V. If an 800 mV p-p differential swing is desired, the total output current of the driver is 16 mA. At balance, the output current is divided evenly between the two sides of the differential signal path, 8 mA to each side. This 8 mA of current flows through the parallel combination of the 55 Ω input termination resistor on the AD8159 and the 50 Ω output termination resistor on the driver, resulting in a common-mode level of

$$V_{TTI} - 8\ mA \times (50\ \Omega \parallel 55\ \Omega) = V_{TTI} - 210\ mV$$

The user can then use Figure 25 to determine the allowable range of values for V_{TTI} that meets the input compliance range based on an 800 mV p-p differential swing.

OUTPUT COMPLIANCE

Figure 43 is depicts the single-ended waveform at the output of the AD8159. The common-mode level (V_{OCM}) and the amplitude ($V_{OSE-BOOST}$) of this waveform are a function of the output tail current (I_T), the output termination supply voltage (V_{TTO}), the topology of the far-end receiver, and whether ac coupling or dc coupling is used. Keep in mind that the output tail current varies with the pre-emphasis level. The user must ensure that the high (V_H) and low (V_L) voltage excursions at the output are within the single-ended absolute voltage range limits as specified in Table 1. Failure to understand the implications of output signal levels and the choice of ac coupling or dc coupling may lead to transistor saturation and poor transmitter performance.

Table 9 and Table 10 show the typical output levels for Port A/Port B and Port C, respectively, where $V_{CC} = V_{TTO} = 3.3$ V, with 50 Ω far-end terminations to a 3.3 V supply.

Figure 43. Single-Ended Output Waveform

Table 9. Output Voltage Levels for Port A and Port B

| PE Setting	I_T (mA)	V_{OSE-DC} (mV p-p)	$V_{OSE-BOOST}$ (mV p-p)	DC-Coupled			AC-Coupled		
				V_{OCM} (V)	V_H (V)	V_L (V)	V_{OCM} (V)	V_H (V)	V_L (V)
0	16	400	400	3.1	3.3	2.9	2.9	3.1	2.7
1	20	400	500	3.05	3.3	2.8	2.8	3.05	2.55
2	24	400	600	3	3.3	2.7	2.7	3	2.4
3	28	400	700	2.95	3.3	2.6	2.6	2.95	2.25

Table 10. Output Voltage Levels for Port C

PE Setting	I_T (mA)	V_{OSE-DC} (mV p-p)	$V_{OSE-BOOST}$ (mV p-p)	DC-Coupled			AC-Coupled		
				V_{OCM} (V)	V_H (V)	V_L (V)	V_{OCM} (V)	V_H (V)	V_L (V)
0	20	400	400	3.05	3.25	2.85	2.8	3	2.6
1	24	400	500	3	3.25	2.75	2.7	2.95	2.45
2	28	400	600	2.95	3.25	2.65	2.6	2.9	2.3
3	32	400	700	2.9	3.25	2.55	2.5	2.85	2.15

Table 11. Symbol Definitions

Symbol	Formula	Definition
V_{OSE-DC}	$I_T\big|_{PE=0} \times 25\ \Omega$	Single-ended output voltage swing after settling
$V_{OSE-BOOST}$	$I_T \times 25\ \Omega$	Boosted single-ended output voltage swing
V_{OCM} (dc-coupled)	$V_{TTO} - I_T/2 \times 25\ \Omega$	Common-mode voltage when the output is dc-coupled
V_{OCM} (ac-coupled)	$V_{TTO} - I_T/2 \times 50\ \Omega$	Common-mode voltage when the output is ac-coupled
V_H	$V_{OCM} + V_{OSE-BOOST}/2$	High single-ended output voltage excursion
V_L	$V_{OCM} - V_{OSE-BOOST}/2$	Low single-ended output voltage excursion

OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MS-026-AED-HD
