

Dual, 2MSPS, 12-Bit, 2 + 2 or 3 + 3 Channel, Simultaneous Sampling ANALOG-TO-DIGITAL CONVERTER

Check for Samples: [ADS7863](#)

FEATURES

- Four Fully- or Six Pseudo-Differential Inputs
- SNR: 71dB, THD: –81dB
- Programmable and Buffered Internal 2.5V Reference
- Flexible Power-Down Features
- Variable Power-Supply Ranges: 2.7V to 5.5V
- Low-Power Operation: 45mW at 5V
- Operating Temperature Range: –40°C to +125°C
- Pin-Compatible with [ADS7861](#) and [ADS8361](#) (SSOP package)

APPLICATIONS

- Motor Control
- Multi-Axis Positioning Systems
- Three-Phase Power Control

DESCRIPTION

The ADS7863 is a dual, 12-bit, 2MSPS, analog-to-digital converter (ADC) with four fully differential or six pseudo-differential input channels grouped into two pairs for high-speed, simultaneous signal acquisition. Inputs to the sample-and-hold (S/H) amplifiers are fully differential and are maintained differential to the input of the ADC. This architecture provides excellent common-mode rejection of 72dB at 100kHz, which is a critical performance characteristic in noisy environments.

The ADS7863 is pin-compatible with the [ADS7861](#), but offers additional features such as a programmable reference output, flexible supply voltage (2.7V to 5.5V for AV_{DD} and BV_{DD}), a pseudo-differential input multiplexer with three channels per ADC, and several power-down features.

The ADS7863 is offered in an SSOP-24 and a 4x4mm QFN-24 package. It is specified over the extended operating temperature range of –40°C to +125°C.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

DEVICE INFORMATION

PIN DESCRIPTIONS

PIN NUMBER		NAME	DESCRIPTION
SSOP	QFN		
1	17	BGND	Buffer I/O ground. Connect to digital ground plane.
2	18	CHB1+	Noninverting analog input channel B1
3	19	CHB1–	Inverting analog input channel B1
4	20	CHB0+	Noninverting analog input channel B0
5	21	CHB0–	Inverting analog input channel B0
6	22	CHA1+	Noninverting analog input channel A1
7	23	CHA1–	Inverting analog input channel A1
8	24	CHA0+	Noninverting analog input channel A0
9	1	CHA0–	Inverting analog input channel A0
10	2	REF _{IN}	Reference voltage input. A ceramic capacitor of 470nF (min) is required at this terminal.
11	3	REF _{OUT}	Reference voltage output. The programmable internal voltage reference output is available on this pin.
12	4	AGND	Analog ground. Connect to analog ground plane.
13	5	AV _{DD}	Analog power supply, 2.7V to 5.5V. Decouple to AGND with a 1μF ceramic capacitor.
14	6	M1	Mode pin 1. Selects between the SDOx digital outputs (see Table 8).
15	7	M0	Mode pin 0. Selects between analog input channels (see Table 8).
16	8	SDI	Serial data input. This pin allows the additional features of the ADS7863 to be used but can also be used in ADS7861-compatible manner.
17	9	CONVST	Conversion start. The ADC switches from the sample into the hold mode on the rising edge of CONVST, independent of the status of CLOCK. The conversion itself starts with the next rising edge of CLOCK.
18	10	RD	Read data. Synchronization pulse for the SDOx outputs and SDI input. RD only triggers when CS is low.
19	11	CS	Chip select. When low, the SDOx outputs are active; when high, the SDOx outputs 3-state.
20	12	CLOCK	External clock input
21	13	BUSY	ADC busy indicator. BUSY goes high when the inputs are in hold mode and returns to low after the conversion has been finished.
22	14	SDOB	Serial data output for converter B. Data are valid on the falling edge of CLOCK.
23	15	SDOA	Serial data output for converter A. When M1 is high, both SDOA and SDOB are active. Data are valid on the falling edge of CLOCK.
24	16	BV _{DD}	Buffer I/O supply, 2.7V to 5.5V. Decouple to BGND with a 1μF ceramic capacitor.

Equivalent Input Circuit

TIMING CHARACTERISTICS

Figure 1. Detailed Timing Diagram (Mode I)

TIMING CHARACTERISTICS (continued)

NOTE: All CONVST commands that occur more than 10ns before the rising edge of cycle '1' of the external clock (Region 'A') initiate a conversion on the rising edge of cycle '1'. All CONVST commands that occur 5ns after the rising edge of cycle '1' or 10ns before the rising edge of cycle 2 (Region 'B') initiate a conversion on the rising edge of cycle '2'. All CONVST commands that occur 5ns after the rising edge of cycle '2' (Region 'C') initiate a conversion on the rising edge of the next clock period.

The CONVST pin should never be switched from LOW to HIGH in the region 10ns prior to the rising edge of the CLOCK and 5ns after the rising edge (gray areas). If CONVST is toggled in this gray area, the conversion could begin on either the same rising edge of the CLOCK or the following edge.

Figure 2. CONVST Timing

TIMING REQUIREMENTS⁽¹⁾

Over recommended operating free-air temperature range at -40°C to $+125^{\circ}\text{C}$, $\text{AV}_{\text{DD}} = 5\text{V}$, and $\text{BV}_{\text{DD}} = 2.7\text{V}$ to 5V , unless otherwise noted.

SYMBOL	PARAMETER	COMMENTS	ADS7863		UNIT
			MIN	MAX	
t_{CONV}	Conversion time	$f_{\text{CLOCK}} = 32\text{MHz}$	406.25		ns
t_{ACQ}	Acquisition time	$f_{\text{CLOCK}} = 32\text{MHz}$	62.5		ns
f_{CLOCK}	CLOCK frequency	See Figure 1	1	32	MHz
t_{CLOCK}	CLOCK period	See Figure 1	31.25	1000	ns
t_{CKL}	CLOCK low time	See Figure 1	9.4		ns

APPLICATIONS INFORMATION

GENERAL DESCRIPTION

The ADS7863 includes two 12-bit analog-to-digital converters (ADCs) that operate based on the successive-approximation register (SAR) principle. The ADCs sample and convert simultaneously. Conversion time can be as low as 406.25ns. Adding the acquisition time of 62.5ns and an additional clock cycle for setup/hold time requirements and skew results in a maximum conversion rate of 2MSPS.

Each ADC has a fully differential, 2:1 multiplexer front-end. In many common applications, all negative input signals remain at the same constant voltage (for example, 2.5V). In this type of application, the multiplexer can be used in a pseudo-differential 3:1 mode, where CHx0– functions as a common-mode input and the remaining three inputs (CHx0+, CHx1–, and CHx1+) operate as separate inputs referred to the common-mode input.

The ADS7863 also includes a 2.5V internal reference. The reference drives a 10-bit digital-to-analog converter (DAC), allowing the voltage at the REF_{OUT} pin to be adjusted via the serial interface in 2.44mV steps. A low-noise operational amplifier with unity gain buffers the DAC output voltage and drives the REF_{OUT} pin.

The ADS7863 offers a serial interface that is compatible with the [ADS7861](#). However, instead of the A0 pin of the ADS7861 that controls the channel selection, the ADS7863 offers a serial data input (SDI) pin that supports additional functions described in the [Digital](#) section of this data sheet (see also the [ADS7861 Compatibility](#) section).

ANALOG

This section addresses the analog input circuit, the ADCs, and the reference design of the device.

Analog Inputs

Each ADC is fed by an input multiplexer; see [Figure 31](#). Each multiplexer is either used in a fully-differential 2:1 configuration (as described in [Table 1](#)) or a pseudo-differential 3:1 configuration (as shown in [Table 2](#)). The channel selection is performed using bits C1 and C0 in the SDI register (see also the [Serial Data Input](#) section).

Figure 31. Input Multiplexer Configuration

The input path for the converter is fully differential and provides a common-mode rejection of 72dB at 100kHz. The high CMRR also helps suppress noise in harsh industrial environments.

Table 1. Fully Differential 2:1 Multiplexer Configuration

C1	C0	ADC+	ADC–
0	0	CHx0+	CHx0–
1	1	CHx1+	CHx1–

Table 2. Pseudo-Differential 3:1 Multiplexer Configuration

C1	C0	ADC+	ADC–
0	0	CHx0+	CHx0–
0	1	CHx1–	CHx0–
1	0	CHx1+	CHx0–

Each of the 2pF sample-and-hold capacitors (shown as C_S in the [Equivalent Input Circuit](#)) is connected via switches to the multiplexer output. Opening the switches holds the sampled data during the conversion process. After finishing the conversion, both capacitors are pre-charged for the duration of one clock cycle to the voltage present at the REF_{IN} pin. After the pre-charging, the multiplexer outputs are connected to the sampling capacitors again. The voltage at the analog input pin is usually different from the reference voltage; therefore, the sample capacitors must be charged to within one-half LSB for 12-bit accuracy during the acquisition time t_{ACQ} (see the [Timing Characteristics](#)).

Acquisition time is indicated with the BUSY signal being held low. It starts by closing the input switches (after finishing the previous conversion and pre-charging) and finishes with the rising edge of the CONVST signal. If the ADS7863 operates at full speed, the acquisition time is typically 62.5ns.

The minimum –3dB bandwidth of the driving operational amplifier can be calculated as shown in [Equation 1](#), with $n = 12$ being the resolution of the ADS7863:

$$f_{-3dB} = \frac{\ln(2) \times (n + 1)}{2\pi \times t_{ACQ}} \quad (1)$$

With $t_{ACQ} = 62.5\text{ns}$, the minimum bandwidth of the driving amplifier is 23MHz. The required bandwidth can be lower if the application allows a longer acquisition time.

A gain error occurs if a given application does not fulfill the settling requirement shown in [Equation 1](#). As a result of precharging the capacitors, linearity and THD are not directly affected, however.

The [OPA365](#) from Texas Instruments is recommended as a driver; in addition to offering the required bandwidth, it provides a low offset and also offers excellent THD performance.

The phase margin of the driving operational amplifier is usually reduced by the ADC sampling capacitor. A resistor placed between the capacitor and the amplifier limits this effect; therefore, an internal 200Ω resistor (R_{SER}) is placed in series with the switch. The switch resistance (R_{SW}) is typically 50Ω (see [Equivalent Input Circuit](#)).

The differential input voltage range of the ADC is $\pm V_{REF}$, the voltage at the REF_{IN} pin.

It is important to keep the voltage to all inputs within the 0.3V limit below AGND and above AV_{DD} while not allowing dc current to flow through the inputs. Current is only necessary to recharge the sample-and-hold capacitors.

Analog-to-Digital Converter (ADC)

The ADS7863 includes two SAR-type, 2MSPS, 12-bit ADCs (shown in the functional block diagram on the front page of this data sheet).

CONVST

The analog inputs are held with the rising edge of the CONVST (conversion start) signal. The setup time of CONVST referred to the next rising edge of CLOCK (system clock) is 10ns (minimum). The conversion automatically starts with the rising CLOCK edge. CONVST should not be issued during a conversion, that is, when BUSY is high.

RD (read data) and CONVST can be shorted to minimize necessary software and wiring. The RD signal is triggered by the ADS7863 on the falling edge of CLOCK. Therefore, the combined signals must be activated with the rising CLOCK edge. The conversion then starts with the subsequent rising CLOCK edge.

CLOCK

The ADC uses an external clock in the range of 1MHz to 32MHz. 12 clock cycles are needed for a complete conversion; the following clock cycle is used for pre-charging the sample capacitors and a minimum of two clock cycles are required for the sampling. With a minimum of 16 clocks used for the entire process, one clock cycle is left for the required setup and hold times along with some margin for delay caused by layout. The clock input can remain low between conversions (after applying the 16th falling edge to complete a running conversion). It can also remain low after applying the 14th falling edge during a DAC register write access if the device is not required to perform a conversion on CHBx (for example, during an initiation phase after power-up).

The CLOCK duty cycle should be 50%. However, the ADS7863 functions properly with a duty cycle between 30% and 70%.

RESET

The ADS7863 features an internal power-on-reset (POR) function. When the device is powered up, the POR sets the device in default mode when the AVDD reaches 1.8V. An external software reset can be issued using SDI register bits A[2:0] (see the [Digital](#) section).

REF_{IN}

The reference input is not buffered and is directly connected to the ADC. The converter generates spikes on the reference input voltage because of internal switching. Therefore, an external capacitor to the analog ground (AGND) should be used to stabilize the reference input voltage. This capacitor should be at least 470nF. Ceramic capacitors (X5R type) with values up to 1μF are commonly available as SMD in 0402 size.

REF_{OUT}

The ADS7863 includes a low-drift, 2.5V internal reference source. This source feeds a 10-bit string DAC that is controlled via the serial interface. As a result of this architecture, the voltage at the REF_{OUT} pin is programmable in 2.44mV steps and can be adjusted to specific application requirements without the use of additional external components.

However, the DAC output voltage should not be programmed below 0.5V to ensure the correct functionality of the reference output buffer. This buffer is connected between the DAC and the REF_{OUT} pin, and is capable of driving the capacitor at the REF_{IN} pin. A minimum of 470nF is required to keep the reference stable (see the previous discussion of REF_{IN} above). For applications that use an external reference source, the internal reference can be disabled using bit RP in the SDI Register (see the [Digital](#) section). The settling time of the REF_{OUT} pin is 500μs, maximum with the reference capacitor connected. The default value of the REF_{OUT} pin after power-up is 2.5V.

For operation with a 2.7V analog supply and a 2.5V reference, the internal reference buffer requires a rail-to-rail input and output. Such buffers typically contain two input stages; when the input voltage passes the mid-range area, a transition occurs at the output because of switching between the two input stages. In this voltage range, rail-to-rail amplifiers generally show a very poor power-supply rejection.

As a result of this poor performance, the ADS7863 buffer has a fixed transition at DAC code 509 (0x1FD). At this code, the DAC may show a jump of up to 10mV in its transfer function.

DIGITAL

This section addresses the timing and control of the ADS7863 serial interface.

Serial Data Input (SDI)

The serial data input or SDI pin is coupled to RD and clocked into the ADS7863 on each falling edge of CLOCK. The data word length of the SDI Register is 12 bits. [Table 3](#) shows the register structure. The data must be transferred MSB-first. [Table 4](#) through [Table 6](#) describe specific bits of this register. The default value of this register after power-up is 0x000.

All additional features become active with the rising edge of the 12th CLOCK signal after issuing the RD pulse.

The reference DAC is controlled by the 12-bit DAC register that can also be accessed using the SDI pin (see [Figure 40](#) for details). [Table 7](#) shows the content of this register; the default value after power-up is 0x3FF.

Serial Data Output (SDOx)

Converted data on the SDOx pins become valid with the third falling CLOCK edge after generating an RD pulse. The following sections explain the different modes of operation in detail.

The digital output code format of the ADS7863 is binary twos complement, as shown in [Table 9](#). Conversion results can be read out multiple times until a new conversion is issued from the CONVST input.

Timing and Control

IMPORTANT:

Consider the Detailed Timing Diagram ([Figure 1](#)) and CONVST timing diagram ([Figure 2](#)) shown in the [Timing Characteristics](#) section. For maximum data throughput, the descriptions and diagrams given in this data sheet assume that the CONVST and RD pins are tied together. Note that they can also be controlled independently.

The operation of the ADS7863 can be configured in four different modes by using the mode pins M0 and M1, as shown in [Table 8](#).

Pin M0 sets either manual or automatic channel selection. In manual mode, the SDI register bits C[1:0] are used to select between channels CHx0 and CHx1; in automatic operation, the SDI register bits C[1:0] are ignored and channel selection is controlled by the device after each conversion. Pin M1 selects between serial data being transmitted simultaneously on both outputs SDOA and SDOB for each channel respectively, or using only the SDOA output for transmitting data from both channels (see [Figure 32](#) through [Figure 39](#) and the associated text for more information).

Table 8. M0/M1 Truth Table

M0	M1	CHANNEL SELECTION	SDOx USED
0	0	Manual (via SDI)	SDOA and SDOB
0	1	Manual (via SDI)	SDOA only
1	0	Automatic	SDOA and SDOB
1	1	Automatic	SDOA only

Additionally, the SDI pin is used for controlling device functionality; see the [Serial Data Input](#) section for details.

Table 9. ADS7863 Output Data Format

DESCRIPTION	DIFFERENTIAL INPUT VOLTAGE (CHXX+) – (CHXX–)	INPUT VOLTAGE AT CHXX+ (CHXX– = V_{REF} = 2.5V)	BINARY CODE	HEXADECIMAL CODE
Positive full-scale	V_{REF}	5V	0111 1111 1111	7FF
Mid-scale	0V	2.5V	0000 0000 0000	000
Mid-scale – 1LSB	$-V_{REF}/4096$	2.49878V	1111 1111 1111	FFF
Negative full-scale	$-V_{REF}$	0V	1000 0000 0000	800

MODE I

With the M0 and M1 pins both set to '0', the ADS7863 enters manual channel control operation and outputs data on both SDOA and SDOB, respectively. The SDI pin switches between the channels. A conversion is initiated by bringing CONVST high.

16 clock cycles are required to perform a single conversion. With the rising edge of CONVST, the ADS7863 switches asynchronously to the external CLOCK from sample to hold mode.

After some delay (t_{12}), the BUSY output pin goes high and remains high for the duration of the conversion cycle. On the falling edge of the second CLOCK cycle, the ADS7863 latches in the channel for the next conversion cycle, depending on the status of the SDI Register bits C[1:0]. CS must be brought low to enable both serial outputs. Data are valid on the falling edge of every 16 clock cycles per conversion. The first two bits are set to '0'. The subsequent data contain the 12-bit conversion result (the most significant bit is transferred first), followed by two '0's (see Figure 1 and Figure 32).

Figure 32. Mode I Timing Diagram (M0 = 0; M1 = 0)

MODE II

With M0 = '0' and M1 set to '1', the ADS7863 also operates in manual channel control mode and outputs data on the SDOA pin only while SDOB is set to 3-state. All other pins function in the same manner as they do in Mode I.

Because it takes 32 clock cycles to output the results

from both ADCs (instead of 16 cycles, if M1 = '0'), the ADS7863 requires 1.0µs to perform a complete conversion/read cycle. If the CONVST signal is issued every 0.5µs (required for the RD signal) as in Mode I, every second pulse is ignored; see Figure 33.

The output data consist of a '0' followed by an ADC indicator ('0' for CHAx or '1' for CHBx), 12 bits of conversion results, and another '00'.

Figure 33. Mode II Timing Diagram (M0 = 0; M1 = 1)

MODE III

With M0 set to '1' and M1 = '0', the ADS7863 automatically cycles between the differential inputs (ignoring the SDI register bits C[1:0]) while offering the conversion result of CHAx on SDOA and the conversion result of CHBx on SDOB (see [Figure 34](#)).

Output data consist of a channel indicator ('0' for CHx0 or '1' for CHx1), followed by a '0', 12 bits of conversion results, and another '00'.

Figure 34. Mode III Timing Diagram (M0 = 1; M1 = 0)

MODE IV

In the same way as Mode II, Mode IV uses the SDOA output line exclusively to transmit data while the differential channels are switched automatically. Following the first conversion after M1 goes high, the SDOB output 3-states (see Figure 35).

Output data consist of a channel indicator ('0' for CHx0 or '1' for CHx1), followed by the ADC indicator ('0' for CHAx or '1' for CHBx), 12 bits of conversion results, and end with '00'.

Figure 35. Mode IV Timing Diagram (M0 = 1 ; M1 = 1)

SPECIAL MODE II (Not ADS7861-Compatible)

For Mode II, a special read mode is available in the ADS7863 where both data results can be read out, triggered by a single RD pulse. To activate this mode, bit S4 in the SDI Register must be set to '1' (see also the [Serial Data Input](#) section).

The CONVST and RD pins can remain tied together, but do not need to be issued every 16 CLOCK cycles. Output data are presented on both terminals, SDOA and SDOB. [Figure 36](#) illustrates the special read mode.

Figure 36. Special Mode II Timing Diagram (M0 = 0; M1 = 1; S4 = 1)

SPECIAL MODE IV (Not ADS7861-Compatible)

Analogous to Special Mode II, the ADS7863 also offers a special read mode for Mode IV in which both data results of a conversion can be read, triggered by a single RD pulse. In this case as well, bit S4 in the SDI register must be set to '1' while the CONVST and RD pins can still be tied together.

As with Special Mode II, these two pins do not need to be issued every 16 CLOCK cycles. Data are available on the SDOA pin.

This special read mode (shown in Figure 37) is not available in Mode I or Mode III.

Figure 37. Special Mode IV Timing Diagram (M0 = 1; M1 = 1; S4 = 1)

PSEUDO-DIFFERENTIAL MODE I (Not ADS7861-Compatible)

In Mode I, the ADS7863 input multiplexers can also operate in a pseudo-differential manner. In this case, SDI bits C[1:0] are used to choose the channels accordingly.

For more details, see the [Serial Data Input](#) section. Data are available on both output terminals, SDOA and SDOB.

The input multiplexer cannot be used for pseudo-differential signals in Mode III or Mode IV.

Figure 38. Pseudo-Differential Mode I (M0 = 0; M1 = 0)

PSEUDO-DIFFERENTIAL MODE II (Not ADS7861-Compatible)

In Mode II, the ADS7863 input multiplexers can also operate in a pseudo-differential configuration. In this case, output data are available on terminal SDOA only, while SDOB is held in 3-state.

Channel switching is performed by setting the C[1:0] bits in the SDI Register accordingly (see also the [Serial Data Input](#) section).

The input multiplexer cannot be used for pseudo-differential signals in Mode III or Mode IV.

Figure 39. Pseudo-Differential Mode II (M0 = 0; M1 = 1)

Programming the Reference DAC (Not ADS7861-Compatible)

The internal reference DAC can be set by issuing an RD pulse while providing an SDI word with P[1:0] = '01' and A[2:0] = '001'. Thereafter, a second RD pulse must be generated with an SDI word starting with the first two bits being ignored, followed by the actual 10-bit DAC value (see Figure 40).

To verify the DAC setting, an RD pulse must be generated while providing an SDI word containing

P[1:0] = '01' and A[2:0] = '011' to initialize the DAC read access. Triggering the RD line again causes the SDOA output to send '0000' followed by the 10-bit DAC value and another '00'. During the second RD access, data present on SDI are ignored, while in Mode I and Mode III valid conversion data for channel B are present on SDOB; the conversion results of channel A are lost. The default value of the DAC register after power-up is 0x3FF, corresponding to a reference voltage of 2.5V on the REF_{OUT} pin.

Figure 40. DAC Write and Read Access Timing Diagram

Power-Down Modes and Reset (Not ADS7861-Compatible)

The ADS7863 has a comprehensive built-in power-down feature. There are three power-down modes: deep power-down, nap power-down, and auto-nap power-down. All three power-down modes are activated with the 12th falling CLOCK edge of the SDI access, during which the related bit asserts (DP = '1', N = '1', or AN = '1'). All modes are deactivated by de-asserting the respective bit in the SDI Register. Contents of the SDI Register are not affected by any of the power-down modes. Any ongoing conversion aborts when deep or nap power-down is initiated. [Table 10](#) lists the differences among the three power-down modes.

In **deep power-down mode**, all functional blocks except the digital interface are disabled. The analog block has its bias currents turned off. In this mode, the power dissipation reduces to 1 μ A within 2 μ s. The wake-up time from deep power-down mode is 1 μ s.

In **nap power-down mode**, the ADS7863 turns off the biasing of the comparator and the mid-voltage buffer within 200ns. The device goes into nap power-down mode regardless of the conversion state.

The **auto-nap power-down mode** is very similar to the nap mode. The only differences are the methods of powering down and waking up the device. The SDI Register bit AN is only used to enable/disable this feature. If the auto-nap mode is enabled, the ADS7863 turns off the biasing automatically after finishing a conversion; thus, the end of conversion actually activates the auto-nap power-down. The device powers down within 200ns in this mode, as well. Triggering a new conversion by applying a CONVST pulse puts the device back into normal operation and automatically starts a new conversion six CLOCK cycles later. Therefore, a complete conversion cycle takes 19 CLOCK cycles; thus, the maximum throughput rate in auto-nap power-down mode is reduced to 1.68MSPS.

To issue a **device reset**, an RD pulse must be generated along with an SDI word containing A[2:0] = '101'. With the 12th falling edge after generating the RD pulse, the entire device—including the serial interface—is forced into reset. After approximately 500ns, the serial interface becomes active again.

Table 10. Power-Down Modes

POWER-DOWN TYPE	ENABLED BY	ACTIVATED BY	ACTIVATION TIME	RESUMED BY	REACTIVATION TIME	DISABLED BY
Deep	DP = '1'	13th clock	2 μ s	DP = '0'	1 μ s	DP = '0'
Nap	N = '1'	13th clock	200ns	N = '0'	3 clocks	N = '0'
Auto-nap	AN = '1'	Each end of conversion	200ns	CONVST pulse	3 clocks	AN = '0'

ADS7861 COMPATIBILITY

The ADS7863IDBQ is pin-compatible with the ADS7861E/EB/EG4. However, there are some differences between the two devices that must be considered when migrating from the ADS7861 to the ADS7863 in an existing design.

SDI versus A0

One of the differences is that pin 16 (A0), which updates the internal SDI register of the ADS7863, is used in conjunction with M0 to select the input channel on the ADS7861.

If, in an existing design, the ADS7861 is used in two-channel mode (M0 = '0') and the status of the A0 pin is unchanged within the first four clock cycles after issuing a conversion start (rising edge of CONVST), the ADS7863 would act similarly to the ADS7861 and convert either channels CHx0 (if SDI is held low during the entire period) or channels CHx1 (if SDI is held high during the entire period). [Figure 33](#) describes the behavior of the ADS7863 in such a situation.

The ADS7863 can also be used to replace the ADS7861 when run in four-channel mode (M0 = '1'). In this case, the A0 pin is held static (high or low) which is also required in the case of SDI to prevent accidental update of the SDI register.

In both cases described above, the additional features of the ADS7863 (pseudo-differential input mode, programmable reference voltage output, and the different power-down modes) could not be accessed but the hardware and software would remain backward-compatible to the ADS7861.

REF_{IN}

The ADS7863 offers an unbuffered REF_{IN} input with a code-dependent input impedance while featuring a programmable and buffered reference output (REF_{OUT}). The ADS7861 offers a high-impedance (buffered) reference input. If an existing ADS7861-based design uses the internal reference of the device and relies on an external resistor divider to adjust the input voltage range of the ADC, migration to ADS7863 requires one of the following conditions:

- a software change to setup the internal reference DAC properly via SDI while removing the external resistors; **or**
- an additional external buffer between the resistor divider and the required 470nF (minimum) capacitor on the REF_{IN} input.

In the latter case, while the capacitor stabilizes the reference voltage during the entire conversion, the buffer has to re-charge it by providing an average current only; thus the required minimum bandwidth of the buffer can be calculated using [Equation 2](#):

$$f_{-3dB} = \frac{\ln(2) \times 2}{2\pi \times 16 \times T_{CLK}} \quad (2)$$

The buffer must also be capable of driving the 470nF load while maintaining its stability.

Timing

The only timing requirement that may cause the ADS7863 to malfunction in an existing ADS7861-based design is the CONVST high time (t₁) which is specified to be 20ns minimum while the ADS7861 works properly with a pulse as short as 15ns. All the other required minimum setup and hold times are specified to be either the same as or lower than the ADS7863; therefore, there are no conflicts with the ADS7861 requirements.

APPLICATION INFORMATION

The absolute minimum configuration of the ADS7863 is shown in Figure 41. In this case, the ADS7863 is used in dual-channel mode only, with the default settings of the device after power up.

The input signal for the amplifiers must fulfill the common-mode voltage requirements of the ADS7863 in this configuration. The actual values of the resistors and capacitors depend on the bandwidth and performance requirements of the application.

Those values can be calculated using Equation 3, with $n = 12$ being the resolution of the ADS7863.

$$f_{\text{FILTER}} = \frac{\ln(2) \times (n + 1)}{2 \times \pi \times 2 \times R \times C} \quad (3)$$

It is recommended to use a capacitor value of at least 20pF.

Keep the acquisition time in mind; the resistor value can be calculated as shown in Equation 4 for each of the series resistors (with $n = 12$, being the resolution of the ADS7863).

$$R = \frac{t_{\text{ACQ}}}{\ln(2) \times (n + 1) \times 2 \times C} \quad (4)$$

Figure 41. Minimum ADS7863 Configuration

LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS7863 circuitry. This condition is particularly true if the CLOCK input is approaching the maximum throughput rate. In this case, it is recommended to have a fixed phase relationship between CLOCK and CONVST. The best performance can be achieved when the digital interface is run in SPI mode; thus, the CLOCK signal is switched off after the 16th cycle and remains low when CONVST is issued.

Additionally, the basic SAR architecture is quite sensitive to glitches or sudden changes on the power supply, reference, ground connections, and digital inputs that occur just before latching the output of the analog comparator. Therefore, when driving any single conversion for an n -bit SAR converter, there are n windows in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, or high-power devices. The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. These errors can change if the external event also changes in time with respect to the CLOCK input.

With this possibility in mind, power to the ADS7863 should be clean and well-bypassed. A 0.1 μ F ceramic bypass capacitor should be placed as close to the device as possible. In addition, a 1 μ F to 10 μ F capacitor is recommended. If needed, an even larger capacitor and a 5 Ω or 10 Ω series resistor may be used to low-pass filter a noisy supply.

If the reference voltage is external and originates from an operational amplifier, be sure that it can drive the reference capacitor without oscillation. The connection between the output of the external reference driver and REF_{IN} should be of low resistance (10 Ω max) to minimize any code-dependent voltage drop on this path.

Grounding

The xGND pins should be connected to a clean ground reference. These connections should be kept as short as possible to minimize the inductance of these paths. It is recommended to use vias connecting the pads directly to the ground plane. In designs without ground planes, the ground trace should be kept as wide as possible. Avoid connections that are too near the grounding point of a microcontroller or digital signal processor.

Depending on the circuit density of the board, placement of the analog and digital components, and the related current loops, a single solid ground plane for the entire printed circuit board (PCB) or a dedicated analog ground area may be used. In an instance of a separated analog ground area, ensure a low-impedance connection between the analog and digital ground of the ADC by placing a bridge underneath (or next to) the ADC. Otherwise, even short undershoots on the digital interface with a value lower than –300mV lead to conduction of ESD diodes, causing current flow through the substrate and degrading the analog performance.

During the PCB layout, care should also be taken to avoid any return currents crossing any sensitive analog areas or signals. No signal must exceed the limit of –300mV with respect to the according ground plane. [Figure 42](#) illustrates the recommended layout of the ground and power-supply connections for both package options.

Supply

The ADS7863 has two separate supplies: the BV_{DD} pin for the digital interface and the AV_{DD} pin for all remaining circuits.

BV_{DD} can range from 2.7V to 5.5V, allowing the ADS7863 to easily interface with processors and controllers. To limit the injection of noise energy from external digital circuitry, BV_{DD} should be filtered properly. Bypass capacitors of 0.1 μ F and 10 μ F should be placed between the BV_{DD} pin and the ground plane.

AV_{DD} supplies the internal analog circuitry. For optimum performance, a linear regulator (for example, the [UA7805](#) family) is recommended to generate the analog supply voltage in the range of 2.7V to 5.5V for the ADS7863 and the necessary analog front-end circuitry.

Bypass capacitors should be connected to the ground plane such that the current is allowed to flow through the pad of the capacitor (that is, the vias should be placed on the opposite side of the connection between the capacitor and the power-supply pin of the ADC).

Digital Interface

To further optimize device performance, a resistor of 10 Ω to 100 Ω can be used on each digital pin of the ADS7863. In this way, the slew rate of the input and output signals is reduced, limiting the noise injection from the digital interface.

Figure 42. Optimized Layout Recommendation

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision D (April 2010) to Revision E Page

- Changed DC Accuracy, G_{ERR} maximum specification in ELectrical Characteristics table [4](#)

Changes from Revision C (April 2009) to Revision D Page

- Deleted footnote 2 from Electrical Characteristics [4](#)
- Replaced [Figure 1](#) [7](#)
- Changed t_9 to t_{12} specifications in the *Timing Requirements* table [8](#)
- Deleted t_{13} specification from the *Timing Requirements* table [8](#)
- Updated *RESET* section of *Applications Information* [16](#)

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

GENERIC PACKAGE VIEW

VQFN - 1 mm max height

PLASTIC QUAD FLATPACK - NO LEAD

Images above are just a representation of the package family, actual package may vary.
Refer to the product data sheet for package details.

4204104/H

VQFN - 1 mm max height

A detailed mechanical drawing of a 24-pin micro connector. The drawing includes a top view, a side view, and a detail view of the terminal.

Top View Dimensions:

- Overall width: 4.1 (3.9)
- Overall height: 4.1 (3.9)
- PIN 1 INDEX AREA: Indicated by a dashed line and an arrow.
- Terminal pitch: 2.5 (2.45 ± 0.1)
- Terminal width: 0.5 (0.45 ± 0.05)
- Terminal height: 0.3 (0.25 ± 0.05)
- Terminal thickness: 0.08 (0.07 ± 0.01)
- Terminal material: C (Copper)

Side View Dimensions:

- Overall height: 1 MAX
- Terminal height: 0.05 (0.04 ± 0.01)
- Terminal thickness: 0.08 (0.07 ± 0.01)
- Terminal material: C (Copper)

Detail View Dimensions:

- Terminal width: 0.5 (0.45 ± 0.05)
- Terminal height: 0.3 (0.25 ± 0.05)
- Terminal thickness: 0.08 (0.07 ± 0.01)
- Terminal material: C (Copper)

Other Callouts:

- SEE TERMINAL DETAIL: Points to the terminal detail view.
- EXPOSED THERMAL PAD: Points to the thermal pad area.
- SYMM: Symmetry symbol.
- PIN 1 ID (OPTIONAL): Points to the pin 1 identification mark.
- 24X 0.3 0.2: Dimension for the terminal pitch and height.
- 24X 0.5 0.3: Dimension for the terminal pitch and width.
- 24X 0.08 C: Dimension for the terminal thickness and material.
- 24X 0.1 (M) C A B: Dimension for the terminal width and material.
- 24X 0.05 (M): Dimension for the terminal thickness.

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

RGE0024B

VQFN - 1 mm max height

PLASTIC QUAD FLATPACK - NO LEAD

LAND PATTERN EXAMPLE
EXPOSED METAL SHOWN
SCALE:15X

4219013/A 05/2017

NOTES: (continued)

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/sluea271).
5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

RGE0024B

VQFN - 1 mm max height

PLASTIC QUAD FLATPACK - NO LEAD

SOLDER PASTE EXAMPLE BASED ON 0.125 mm THICK STENCIL

EXPOSED PAD 25
78% PRINTED SOLDER COVERAGE BY AREA UNDER PACKAGE
SCALE:20X

4219013/A 05/2017

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

DBQ (R-PDSO-G24)

PLASTIC SMALL-OUTLINE PACKAGE

4073301-4/H 10/2008

- NOTES:
- All linear dimensions are in inches (millimeters).
 - This drawing is subject to change without notice.
 - Body dimensions do not include mold flash or protrusion not to exceed 0.006 (0,15) per side.
 - Falls within JEDEC MO-137 variation AE.
