

60V 4-Switch Synchronous Buck-Boost LED Driver Controller

FEATURES

- 4-Switch Single Inductor Architecture Allows V_{IN} Above, Below or Equal to V_{OUT}
- Synchronous Switching: Up to 98.5% Efficiency
- Wide V_{IN} Range: 4.7V to 60V
- Wide V_{OUT} Range: 0V to 60V (52V LED)
- $\pm 6\%$ LED Current Accuracy: $0V \leq V_{LED} < 52V$
- True Color PWM™ and Analog Dimming
- LED and Input Current Regulation with Current Monitor Outputs
- No Top MOSFET Refresh in Buck or Boost
- V_{OUT} Disconnected From V_{IN} During Shutdown
- Open or Shorted LED Fault Protection
- Capable of 100W or Greater per IC
- 38-Lead TSSOP with Exposed Pad

APPLICATIONS

- Automotive Head Lamps/Running Lamps
- General Purpose Lighting

DESCRIPTION

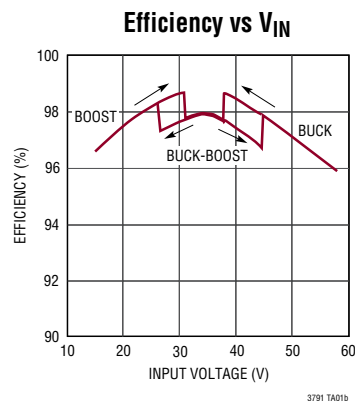

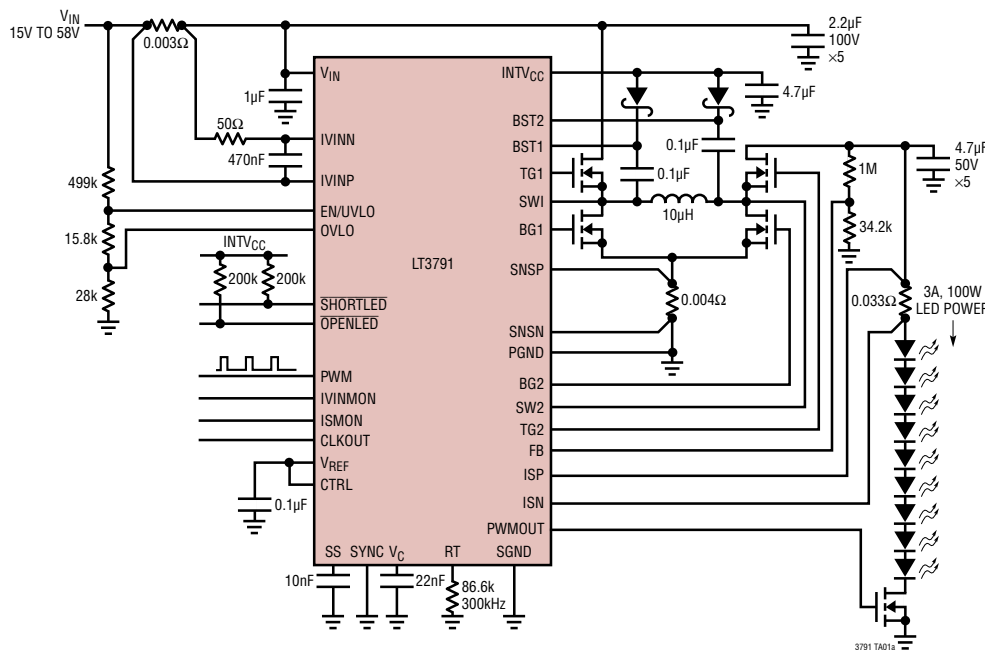

The **LT[®]3791** is a synchronous 4-switch buck-boost LED driver controller. The controller can regulate LED current up to 52V of LED string with input voltages above, below, or equal to the output voltage. The constant-frequency, forced-continuous current mode architecture allows its frequency to be adjusted or synchronized from 200kHz to 700kHz. No top MOSFET refresh switching cycle is needed in buck or boost operation. With 60V input, 60V output capability and seamless transitions between operating regions, the LT3791 is ideal for LED driver applications in automotive, industrial, and even battery-powered systems.

For new designs we recommend the LT8391: 60V synchronous 4-switch, buck-boost LED controller due to its numerous performance improvements over the LT3791.

LT, LT, LTC, LTM, Linear Technology and the Linear logo are registered and True Color PWM is a trademark of Analog Devices, Inc. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

98.5% Efficient 100W (33.3V 3A) Buck-Boost LED Driver

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LT3791E is guaranteed to meet performance from 0°C to 125°C junction temperature. Specification over the -40°C to 125°C operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LT3791I is guaranteed to meet performance specifications over the -40°C to 125°C operating junction temperature range. The LT3791H is guaranteed to meet performance specifications over the -40°C to 150°C

operating junction temperature range. The LT3791MP is guaranteed to meet performance specifications over the -55°C to 150°C operating junction temperature range. High junction temperatures degrade operating lifetimes. Operating lifetime is derated for junction temperatures greater than 125°C .

Note 3: The LT3791 includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed the maximum operating junction temperature when overtemperature protection is active. Continuous operation above the specified absolute maximum operating junction temperature may impair device reliability.

TYPICAL PERFORMANCE CHARACTERISTICS $T_A = 25^\circ\text{C}$, unless otherwise noted.

PIN FUNCTIONS

CTRL (Pin 1): Current Sense Threshold Adjustment Pin for Analog Dimming. Regulating threshold $V_{(ISP-ISN)}$ is 1/10th of ($V_{CTRL} - 200\text{mV}$). CTRL linear range is from 200mV to 1.1V. For $V_{CTRL} > 1.3\text{V}$, the current sense threshold is constant at the full-scale value of 100mV. For $1.1\text{V} < V_{CTRL} < 1.3\text{V}$, the dependence of the current sense threshold upon V_{CTRL} transitions from a linear function to a constant value, reaching 98% of full scale by $V_{CTRL} = 1.2\text{V}$. Connect CTRL to V_{REF} for the 100mV default threshold. Force less than 175mV (typical) to stop switching. Do not leave this pin open.

SS (Pin 2): Soft-start reduces the input power sources surge current by gradually increasing the controller's current limit. A minimum value of 10nF is recommended on this pin. SS is used as a timer when an open or shorted LED condition occurs. A 500k resistor placed from SS to V_{REF} will latch the part off in the event of a fault. If left open, a 1.4μA current source pulls down on SS and the part restarts in a fault.

PWM (Pin 3): A signal low turns off switches, idles switching and disconnects the V_C pin from all external loads. The PWMOUT pin follows the PWM pin. PWM has an internal 100k pull-down resistor. If not used, connect to INTV_{CC}.

OPENLED (Pin 4): An open-drain pull-down on OPENLED asserts if FB is greater than 1.15V (typical) and $V_{(ISP-ISN)}$ is less than 10mV (typical). To function, the pin requires an external pull-up resistor.

SHORTLED (Pin 5): An open-drain pull-down on SHORTLED asserts if FB is less than 400mV (typical). To function, the pin requires an external pull-up resistor.

V_{REF} (Pin 6): Voltage Reference Output Pin, Typically 2V. This pin drives a resistor divider for the CTRL pin, either for analog dimming or for temperature limit/compensation of the LED load. Can supply up to 200μA of current.

ISMON (Pin 7): Monitor pin that produces a voltage that is ten times the voltage $V_{(ISP-ISN)}$. ISMON will equal 1V when $V_{(ISP-ISN)} = 100\text{mV}$.

IVINMON (Pin 8): Monitor pin that produces a voltage that is twenty times the voltage $V_{(IVINP-IVINN)}$. IVINMON will equal 1V when $V_{(IVINP-IVINN)} = 50\text{mV}$.

EN/UVLO (Pin 9): Enable Control Pin. Forcing an accurate 1.2V falling threshold with an externally programmable hysteresis is generated by the external resistor divider and a 3μA pull-down current. Above the 1.2V (typical) threshold (but below 6V), EN/UVLO input bias current is sub-μA. Below the falling threshold, a 3μA pull-down current is enabled so the user can define the hysteresis with the external resistor selection. An undervoltage condition resets soft-start. Tie to 0.3V, or less, to disable the device and reduce V_{IN} quiescent current below 1μA.

IVINP (Pin 10): Positive Input for the Input Current Limit and Monitor. Input bias current for this pin is typically 90μA.

IVINN (Pin 11): Negative Input for the Input Current Limit and Monitor. The input bias current for this pin is typically 20μA.

V_{IN} (Pin 12): Main Input Supply. Bypass this pin to PGND with a capacitor.

INTV_{CC} (Pin 13): Internal 5V Regulator Output. The driver and control circuits are powered from this voltage. Bypass this pin to PGND with a minimum 4.7μF ceramic capacitor.

TG1 (Pin 14): Top Gate Drive. Drives the top N-channel MOSFET with a voltage equal to INTV_{CC} superimposed on the switch node voltage SW1.

BST1 (Pin 15): Bootstrapped Driver Supply. The BST1 pin swings from a diode voltage below INTV_{CC} up to a diode voltage below $V_{IN} + \text{INTV}_{CC}$.

SW1 (Pin 16): Switch Node. SW1 pin swings from a diode voltage drop below ground up to V_{IN} .

PGND (Pins 17, 20): Power Ground. Connect these pins closely to the source of the bottom N-channel MOSFET.

BG1 (Pin 18): Bottom Gate Drive. Drives the gate of the bottom N-channel MOSFET between ground and INTV_{CC}.

BG2 (Pin 19): Bottom Gate Drive. Drives the gate of the bottom N-channel MOSFET between ground and INTV_{CC}.

SW2 (Pin 21): Switch Node. SW2 pin swings from a diode voltage drop below ground up to V_{OUT} .

BST2 (Pin 22): Bootstrapped Driver Supply. The BST2 pin swings from a diode voltage below INTV_{CC} up to a diode voltage below $V_{OUT} + \text{INTV}_{CC}$.

PIN FUNCTIONS

NC (Pin 23): No Connect Pin. Leave this pin floating.

TG2 (Pin 24): Top Gate Drive. Drives the top N-channel MOSFET with a voltage equal to $INTV_{CC}$ superimposed on the switch node voltage SW2.

ISP (Pin 25): Connection Point for the Positive Terminal of the Output Current Feedback Resistor.

ISN (Pin 26): Connection Point for the Negative Terminal of the Output Current Feedback Resistor.

SNSP (Pin 27): The Positive Input to the Current Sense Comparator. The V_C pin voltage and controlled offsets between the SNSP and SNSN pins, in conjunction with a resistor, set the current trip threshold.

SNSN (Pin 28): The Negative Input to the Current Sense Comparator.

TEST1 (Pin 29): This pin is used for testing purposes only and must be connected to SGND for the part to operate properly.

SGND (Pin 30, Exposed Pad Pin 39): Signal Ground. All small-signal components and compensation should connect to this ground, which should be connected to PGND at a single point. Solder the exposed pad directly to the ground plane.

PWMOUT (Pin 31): Buffered Version of PWM Signal for Driving LED Load Disconnect N-Channel MOSFET. The PWMOUT pin is driven from $INTV_{CC}$. Use of a MOSFET with a gate cutoff voltage higher than 1V is recommended.

TEST2 (Pin 32): This pin is used for testing purposes only and must be connected to $INTV_{CC}$ (Pin 13) for the part to operate properly.

CLKOUT (Pin 33): Clock Output Pin. An in-phase clock is provided at the oscillator frequency to allow for synchronizing two devices for extending output power capability.

SYNC (Pin 34): External Synchronization Input Pin. This pin is internally terminated to GND with a 90k resistor. The rising edge will be synchronized with the rising edge of the SYNC signal.

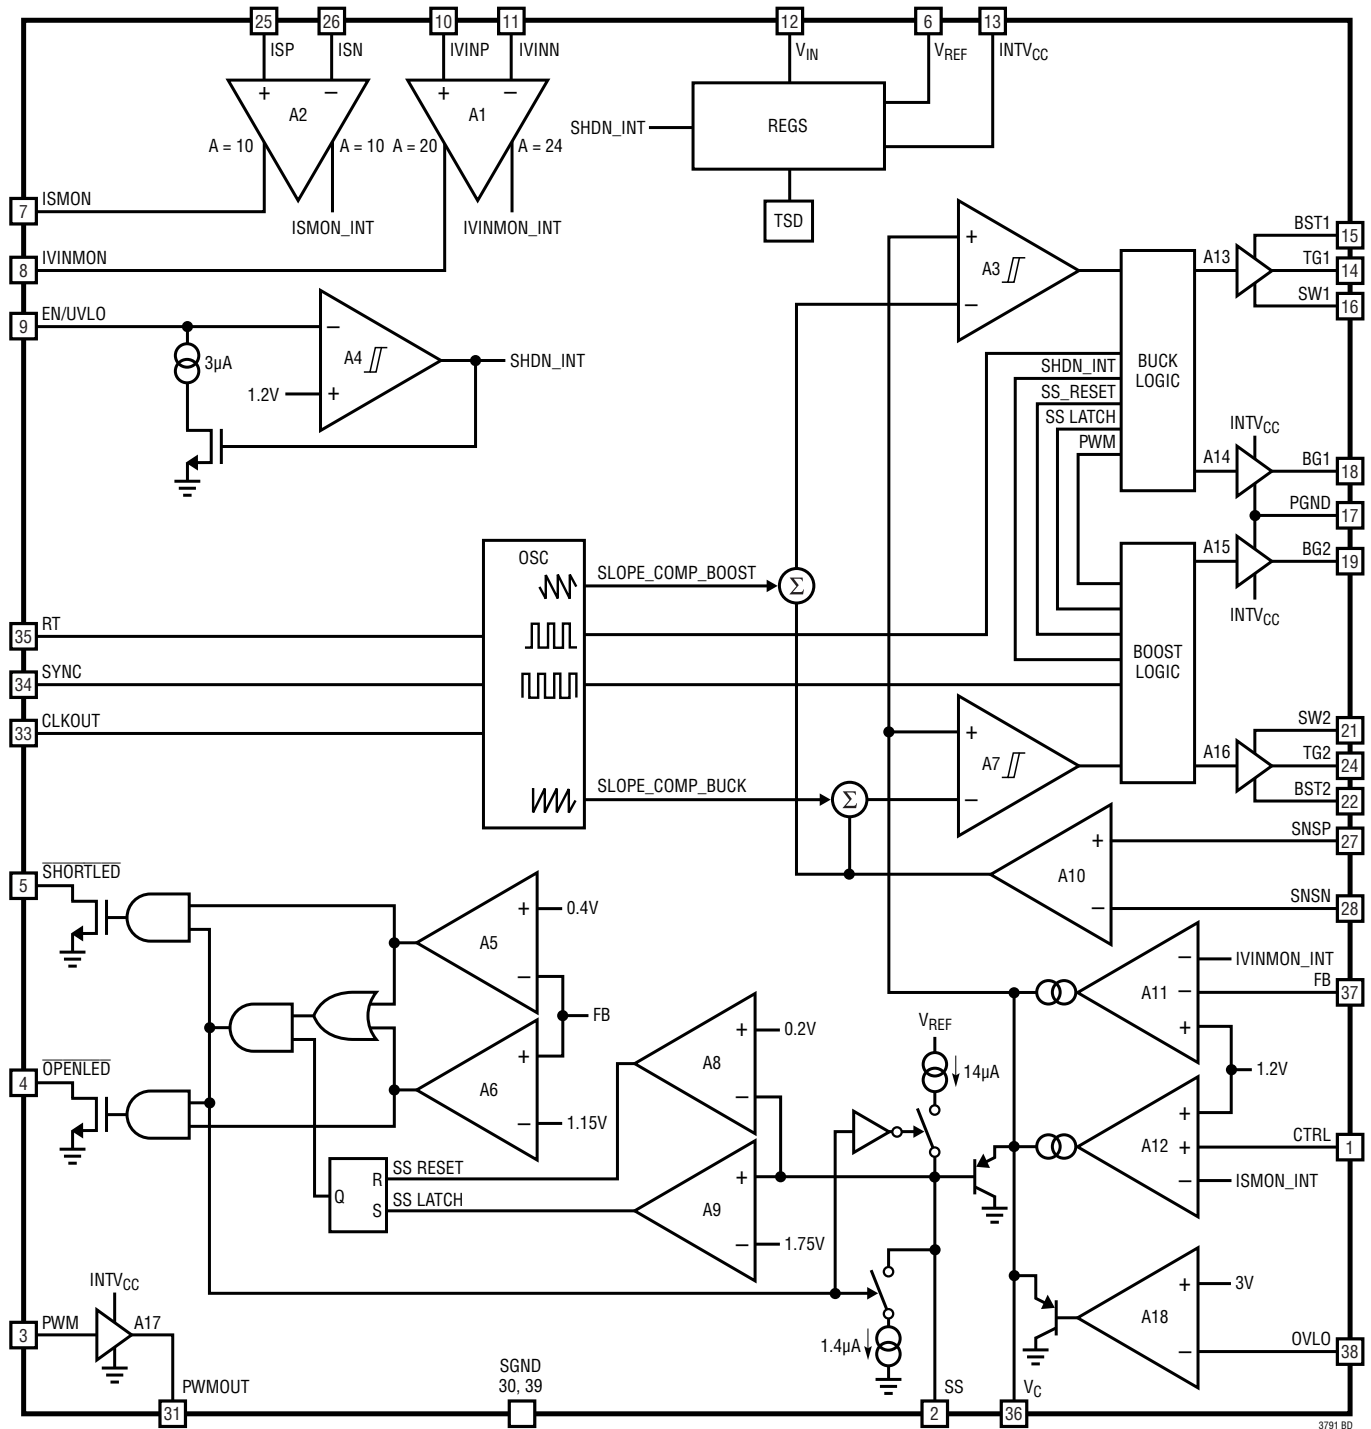

RT (Pin 35): Frequency Set Pin. Place a resistor to GND to set the internal frequency. The range of oscillation is 200kHz to 700kHz.

V_C (Pin 36): Current Control Threshold and Error Amplifier Compensation Point. The current comparator threshold increases with this control voltage. The voltage ranges from 0.7V to 1.9V.

FB (Pin 37): Voltage Loop Feedback Pin. FB is intended for LED protection of an open or shorted LED event. The internal transconductance amplifier with output V_C will regulate FB to 1.2V (typical) through the DC/DC converter. If the FB input is regulating the loop and $V_{(ISP-ISN)} < 10\text{mV}$, the $\overline{\text{OPENLED}}$ pull-down is asserted. If the FB pin is less than 400mV, the $\overline{\text{SHORTLED}}$ pull-down is asserted.

OVLO (Pin 38): Overvoltage Input Pin. This pin is used for OVLO, if $OVLO > 3\text{V}$ then SS is pulled low, the part stops switching and resets. Do not leave this pin open.

BLOCK DIAGRAM

OPERATION

The LT3791 is a current mode controller that provides an output voltage above, equal to or below the input voltage. The LTC proprietary topology and control architecture uses a current sensing resistor in buck or boost operation. The sensed inductor current is controlled by the voltage on the V_C pin, which is the output of the feedback amplifiers A11 and A12. The V_C pin is controlled by three inputs, one input from the output current loop, one input from the input current loop, and the third input from the feedback loop. Whichever feedback input is higher takes precedence, forcing the converter into either a constant-current or a constant-voltage mode.

The LT3791 is designed to transition cleanly between the two modes of operation. Current sense amplifier A1 senses the voltage between the IVINP and IVINN pins and provides a pre-gain to amplifier A11. When the voltage between IVINP and IVINN reaches 50mV, the output of A1 provides IVINMON_INT to the inverting input of A11 and the converter is in constant-current mode. If the current sense voltage exceeds 50mV, the output of A1 increases causing the output of A11 to decrease, thus reducing the amount of current delivered to the output. In this manner the current sense voltage is regulated to 50mV.

The output current amplifier works similar to the input current amplifier but with a 100mV voltage instead of 50mV. The output current sense level is also adjustable by the CTRL pin. Forcing CTRL to less than 1.2V forces ISMON_INT to the same level as CTRL, thus providing current-level control. The output current amplifier provides rail-to-rail operation. Similarly if the FB pin goes above 1.2V the output of A11 decreases to reduce the current level and regulate the output (constant-voltage mode).

The LT3791 provides monitoring pins IVINMON and ISMON that are proportional to the voltage across the input and output current amplifiers respectively.

The main control loop is shut down by pulling the EN/UVLO pin low. When the EN/UVLO pin is higher than 1.2V, an internal 14μA current source charges soft-start capacitor C_{SS} at the SS pin. The V_C voltage is then clamped a diode voltage higher than the SS voltage while the C_{SS} is

slowly charged during start-up. This “soft-start” clamping prevents abrupt current from being drawn from the input power supply. The SS can also be used as a fault timer whenever an open or shorted LED is detected.

The top MOSFET drivers are biased from floating bootstrap capacitors C1 and C2, which are normally recharged through an external diode when the top MOSFET is turned off. Schottky diodes across the synchronous switch M4 and synchronous switch M2 are not required, but they do provide a lower drop during the dead time. The addition of the Schottky diodes typically improves peak efficiency by 1% to 2% at 500kHz.

Power Switch Control

Figure 1 shows a simplified diagram of how the four power switches are connected to the inductor, V_{IN} , V_{OUT} and GND. Figure 2 shows the regions of operation for the LT3791 as a function of duty cycle D. The power switches are properly controlled so the transfer between regions is continuous. When V_{IN} approaches V_{OUT} , the buck-boost region is reached.

Figure 1. Simplified Diagram of the Output Switches

D_{MAX}^{BOOST} (BG2)	BOOST REGION	M1 ON, M2 OFF PWM M3, M4 SWITCHES
D_{MIN}^{BOOST}	BUCK-BOOST REGION	4-SWITCH PWM
D_{MAX}^{BUCK} (TG1)		
D_{MIN}^{BUCK}	BUCK REGION	M4 ON, M3 OFF PWM M2, M1 SWITCHES

3791 F02

Figure 2. Operating Regions vs Duty Cycle

OPERATION

Buck Region ($V_{IN} > V_{OUT}$)

Switch M4 is always on and switch M3 is always off during this mode. At the start of every cycle, synchronous switch M2 is turned on first. Inductor current is sensed when synchronous switch M2 is turned on. After the sensed inductor current falls below the reference voltage, which is proportional to V_C , synchronous switch M2 is turned off and switch M1 is turned on for the remainder of the cycle. Switches M1 and M2 will alternate, behaving like a typical synchronous buck regulator. The duty cycle of switch M1 increases until the maximum duty cycle of the converter in buck operation reaches $D_{MAX(BUCK, TG1)}$, given by:

$$D_{MAX(BUCK, TG1)} = 100\% - D_{(BUCK-BOOST)}$$

where $D_{(BUCK-BOOST)}$ is the duty cycle of the buck-boost switch range:

$$D_{(BUCK-BOOST)} = 8\%$$

Figure 3 shows typical buck operation waveforms. If V_{IN} approaches V_{OUT} , the buck-boost region is reached.

Buck-Boost Region ($V_{IN} \sim V_{OUT}$)

When V_{IN} is close to V_{OUT} , the controller is in buck-boost operation. Figure 4 and Figure 5 show typical waveforms in this operation. Every cycle the controller turns on switches M2 and M4, then M1 and M4 are turned on until 180° later when switches M1 and M3 turn on, and then switches M1 and M4 are turned on for the remainder of the cycle.

Figure 3. Buck Operation ($V_{IN} > V_{OUT}$)

Figure 4. Buck-Boost Operation ($V_{IN} \leq V_{OUT}$)

Figure 5. Buck-Boost Operation ($V_{IN} \geq V_{OUT}$)

OPERATION

Boost Region ($V_{IN} < V_{OUT}$)

Switch M1 is always on and synchronous switch M2 is always off in boost operation. Every cycle switch M3 is turned on first. Inductor current is sensed when synchronous switch M3 is turned on. After the sensed inductor current exceeds the reference voltage which is proportional to V_C , switch M3 turns off and synchronous switch M4 is turned on for the remainder of the cycle. Switches M3 and M4 alternate, behaving like a typical synchronous boost regulator.

The duty cycle of switch M3 decreases until the minimum duty cycle of the converter in boost operation reaches $D_{MIN(BOOST,BG2)}$, given by:

$$D_{MIN(BOOST,BG2)} = D_{(BUCK-BOOST)}$$

where $D_{(BUCK-BOOST)}$ is the duty cycle of the buck-boost switch range:

$$D_{(BUCK-BOOST)} = 8\%$$

Figure 6 shows typical boost operation waveforms. If V_{IN} approaches V_{OUT} , the buck-boost region is reached.

Figure 6. Boost Operation ($V_{IN} < V_{OUT}$)

Low Current Operation

The LT3791 runs in forced continuous mode. In this mode the controller behaves as a continuous, PWM current mode synchronous switching regulator. In boost operation, switch M1 is always on, switch M3 and synchronous switch M4 are alternately turned on to maintain the output voltage independent of the direction of inductor current. In buck operation, synchronous switch M4 is always on, switch M1 and synchronous switch M2 are alternately turned on to maintain the output voltage independent of the direction of inductor current. In the forced continuous mode, the output can source or sink current.

APPLICATIONS INFORMATION

The Typical Application on the front page is a basic LT3791 application circuit. External component selection is driven by the load requirement, and begins with the selection of R_{SENSE} and the inductor value. Next, the power MOSFETs are selected. Finally, C_{IN} and C_{OUT} are selected. This circuit can operate up to an input voltage of 60V.

Programming The Switching Frequency

The RT frequency adjust pin allows the user to program the switching frequency from 200kHz to 700kHz to optimize efficiency/performance or external component size. Higher frequency operation yields smaller component size but increases switching losses and gate driving current, and may not allow sufficiently high or low duty cycle operation. Lower frequency operation gives better performance at the cost of larger external component size. For an appropriate R_T resistor value see Table 1. An external resistor from the RT pin to GND is required; do not leave this pin open.

Table 1. Switching Frequency vs R_T Value

f_{osc} (kHz)	R_T (k Ω)
200	147
300	84.5
400	59.0
500	45.3
600	35.7
700	29.4

Frequency Synchronization

The LT3791 switching frequency can be synchronized to an external clock using the SYNC pin. Driving SYNC with a 50% duty cycle waveform is always a good choice, otherwise maintain the duty cycle between 10% and 90%.

The rising edge of CLK_OUT corresponds to the rising edge of SYNC thus allowing paralleling converters. The falling edge of CLK_OUT turns on switch M3 and the rising edge of CLK_OUT turns on switch M2.

Inductor Selection

The operating frequency and inductor selection are inter-related in that higher operating frequencies allow the use of smaller inductor and capacitor values. The inductor value has a direct effect on ripple current. The maximum inductor current ripple ΔI_L can be seen in Figure 7. This is the maximum ripple that will prevent subharmonic oscillation and also regulate with zero load. The ripple should be less than this to allow proper operation over all load currents. For a given ripple the inductance terms in continuous mode are as follows:

$$L_{BUCK} > \frac{V_{OUT} \cdot (V_{IN(MAX)} - V_{OUT}) \cdot 100}{f \cdot I_{LED} \cdot \%Ripple \cdot V_{IN(MAX)}}$$

$$L_{BOOST} > \frac{V_{IN(MIN)}^2 \cdot (V_{OUT} - V_{IN(MIN)}) \cdot 100}{f \cdot I_{LED} \cdot \%Ripple \cdot V_{OUT}^2}$$

where:

f is operating frequency

% ripple is allowable inductor current ripple

$V_{IN(MIN)}$ is minimum input voltage

$V_{IN(MAX)}$ is maximum input voltage

V_{OUT} is output voltage

I_{LED} is current through the LEDs

APPLICATIONS INFORMATION

Figure 7. Maximum Peak-to-Peak Ripple vs Duty Cycle

For high efficiency, choose an inductor with low core loss. Also, the inductor should have low DC resistance to reduce the I^2R losses, and must be able to handle the peak inductor current without saturating. To minimize radiated noise, use a shielded inductor.

R_{SENSE} Selection and Maximum Output Current

R_{SENSE} is chosen based on the required output current. The current comparator threshold sets the peak of the inductor current in boost operation and the maximum inductor valley current in buck operation. In boost operation, the maximum average load current at $V_{IN(MIN)}$ is:

$$I_{OUT(MAX_BOOST)} = \left(\frac{51mV}{R_{SENSE}} - \frac{\Delta I_L}{2} \right) \cdot \frac{V_{IN(MIN)}}{V_{OUT}}$$

where ΔI_L is peak-to-peak inductor ripple current. In buck operation, the maximum average load current is:

$$I_{OUT(MAX_BUCK)} = \left(\frac{47.5mV}{R_{SENSE}} + \frac{\Delta I_L}{2} \right)$$

The maximum current sensing R_{SENSE} value for the boost operation is:

$$R_{SENSE(MAX)} = \frac{2 \cdot 51mV \cdot V_{IN(MIN)}}{2 \cdot I_{LED} \cdot V_{OUT} + \Delta I_{L(BOOST)} \cdot V_{IN(MIN)}}$$

The maximum current sensing R_{SENSE} value for the buck operation is:

$$R_{SENSE(MAX)} = \frac{2 \cdot 47.5mV}{2 \cdot I_{LED} - \Delta I_{L(BUCK)}}$$

The final R_{SENSE} value should be lower than the calculated $R_{SENSE(MAX)}$ in both the boost and buck operation. A 20% to 30% margin is usually recommended.

C_{IN} and C_{OUT} Selection

In boost operation, input current is continuous. In buck operation, input current is discontinuous. In buck operation, the selection of input capacitor, C_{IN} , is driven by the need to filter the input square wave current. Use a low ESR capacitor sized to handle the maximum RMS current. For buck operation, the input RMS current is given by:

$$I_{RMS} = \sqrt{I_{LED}^2 \cdot D + \frac{\Delta I_L^2}{12} \cdot D}$$

APPLICATIONS INFORMATION

The formula has a maximum at $V_{IN} = 2V_{OUT}$. Note that ripple current ratings from capacitor manufacturers are often based on only 2000 hours of life which makes it advisable to derate the capacitor.

In boost operation, the discontinuous current shifts from the input to the output, so C_{OUT} must be capable of reducing the output voltage ripple. The effects of ESR (equivalent series resistance) and the bulk capacitance must be considered when choosing the right capacitor for a given output ripple voltage. The steady ripple due to charging and discharging the bulk capacitance is given by:

$$\Delta V_{RIPPLE (BOOST_CAP)} = \frac{I_{LED} \cdot (V_{OUT} - V_{IN(MIN)})}{C_{OUT} \cdot V_{OUT} \cdot f}$$

$$\Delta V_{RIPPLE (BUCK_CAP)} \approx \frac{\Delta I_L}{8 \cdot f \cdot C_{OUT}}$$

where C_{OUT} is the output filter capacitor.

The steady ripple due to the voltage drop across the ESR is given by:

$$\Delta V_{BOOST(ESR)} = I_{LED} \cdot ESR$$

$$\Delta V_{BUCK(ESR)} = I_{LED} \cdot ESR$$

Multiple capacitors placed in parallel may be needed to meet the ESR and RMS current handling requirements. Output capacitors are also used for stability for the LT3791. A good starting point for output capacitors is seen in the Typical Applications circuits. Ceramic capacitors have excellent low ESR characteristics but can have a high voltage coefficient and are recommended for applications less than 100W. Capacitors available with low ESR and high ripple current ratings, such as OS-CON and POSCAP may be needed for applications greater than 100W.

Programming V_{IN} UVLO and OVLO

The falling UVLO value can be accurately set by the resistor divider R1 and R2. A small 3 μ A pull-down current is active when the EN/UVLO is below the threshold. The purpose of this current is to allow the user to program the rising hysteresis. The following equations should be used to determine the resistor values:

$$V_{IN(UVLO^-)} = 1.2 \cdot \frac{R1 + R2}{R2}$$

$$V_{IN(UVLO^+)} = 3\mu A \cdot R1 + 1.215 \cdot \frac{R1 + R2}{R2}$$

The rising OVLO value can be accurately set by the resistor divider R3 and R4. The following equations should be used to determine the resistor values:

$$V_{IN(OVLO^+)} = 3 \cdot \frac{R3 + R4}{R4}$$

$$V_{IN(OVLO^-)} = 2.925 \cdot \frac{R3 + R4}{R4}$$

Figure 8. Resistor Connection to Set V_{IN} UVLO and OVLO Thresholds

APPLICATIONS INFORMATION

Programming LED Current

The LED current is programmed by placing an appropriate value current sense resistor, R_{LED} , in series with the LED string. The voltage drop across R_{LED} is (Kelvin) sensed by the ISP and ISN pins. The CTRL pin should be tied to a voltage higher than 1.2V to get the full-scale 100mV (typical) threshold across the sense resistor. The CTRL pin can also be used to dim the LED current, although relative accuracy decreases with the decreasing sense threshold. When the CTRL pin voltage is less than 1V, the LED current is:

$$I_{LED} = \frac{V_{CTRL} - 200\text{mV}}{R_{LED} \cdot 10}$$

When the CTRL pin voltage is between 1.1V and 1.3V the LED current varies with V_{CTRL} , but departs from the equation above by an increasing amount as V_{CTRL} voltage increases. Ultimately, when $V_{CTRL} > 1.3\text{V}$ the LED current no longer varies. The typical $V_{(ISP-ISN)}$ threshold vs V_{CTRL} is listed in Table 2.

Table 2. $V_{(ISP-ISN)}$ Threshold vs CTRL

V_{CTRL} (V)	$V_{(ISP-ISN)}$ (mV)
1.1	90
1.15	94.5
1.2	98
1.25	99.5
1.3	100

When V_{CTRL} is higher than 1.3V, the LED current is regulated to:

$$I_{LED} = \frac{100\text{mV}}{R_{LED}}$$

The CTRL pin should not be left open (tie to V_{REF} if not used). The CTRL pin can also be used in conjunction with a thermistor to provide overtemperature protection for the LED load, or with a resistor divider to V_{IN} to reduce output power and switching current when V_{IN} is low. The presence of a time varying differential voltage signal (ripple) across ISP and ISN at the switching frequency is expected. The amplitude of this signal is increased by high LED load current, low switching frequency and/or a smaller value output filter capacitor. Some level of ripple signal is acceptable: the compensation capacitor on the V_C pin filters the signal so the average difference between ISP and ISN is regulated to the user-programmed value. Ripple voltage amplitude (peak-to-peak) in excess of 20mV should not cause mis-operation, but may lead to noticeable offset between the average value and the user-programmed value.

ISMON

The ISMON pin provides a linear indication of the current flowing through the LEDs. The equation for V_{ISMON} is $V_{(ISP-ISN)} \cdot 10$. This pin is suitable for driving an ADC input, however, the output impedance of this pin is 12.5k Ω so care must be taken not to load this pin.

Programming Input Current Limit

The LT3791 has a standalone current sense amplifier. It can be used to limit the input current. The input current limit is calculated by the following equation:

$$I_{IN} = \frac{50\text{mV}}{R_{IN}}$$

APPLICATIONS INFORMATION

For loop stability a lowpass RC filter is needed. For most applications, a 50Ω resistor and 470nF capacitor is sufficient.

Table 3

R_{IN} (mΩ)	I_{LIMIT} (A)
20	2.5
15	3.3
12	4.2
10	5.0
6	8.3
5	10.0
4	12.5
3	16.7
2	25

IVINMON

The IVINMON pin provides a linear indication of the current flowing through the input. The equation for $V_{IVINMON}$ is $V_{(IVINP-IVINN)} \cdot 20$. This pin is suitable for driving an ADC input, however, the output impedance of this pin is 12.5kΩ so care must be taken not to load this pin.

Programming Output Overvoltage Threshold for Open LED Protection

For an LED driver application with small output capacitors, the output voltage usually overshoots a lot during an open LED event. Although the 1.2V (typical) FB regulation loop tries to regulate the output, the loop is usually too slow to prevent the output from overshooting. Once the FB voltage hits its overvoltage threshold, 1.25V (typical), the LT3791 stops switching by turning TG1, TG2 off, and BG1, BG2 on. In this way, the minimum overshoot is guaranteed.

The output overvoltage threshold can be set by selecting the values of R5 and R6 (see Figure 9) according to the following equation:

$$V_{OUT(OMP)} = 1.25 \cdot \frac{R5 + R6}{R6}$$

Make sure the expected V_{FB} during normal operation does not exceed 1.1V:

$$V_{LED} \cdot \frac{R6}{R5 + R6} \leq 1.1$$

These equations set the maximum LED string voltage with open LED protection for the LT3791 to be 52V.

Dimming Control

There are two methods to control the current source for dimming using the LT3791. One method uses the CTRL pin to adjust the current regulated in the LEDs. A second method uses the PWM pin to modulate the current source between zero and full current to achieve a precisely programmed average current. To make PWM dimming more accurate, the switch demand current is stored on the V_C node during the quiescent phase when PWM is low. This feature minimizes recovery time when the PWM signal goes high. To further improve the recovery time a disconnect switch may be used in the LED current path to prevent the ISP node from discharging during the PWM signal low phase. The minimum PWM on- or off-time is affected by choice of operating frequency and external component selection. The best overall combination of PWM and analog dimming capabilities is available if the minimum PWM pulse is at least six switching cycles and the PWM pulse is synchronized to the SYNC signal.

Figure 9. Resistor Connection for Open LED Protection

APPLICATIONS INFORMATION

SHORTLED Pin

The LT3791 provides an open-drain status pin, $\overline{\text{SHORTLED}}$, which pulls low when the FB pin is below 400mV. The only time the FB pin will be below 400mV is during start-up or if the LEDs are shorted. During start-up the LT3791 ignores the voltage on the FB pin until the soft-start capacitor reaches 1.75V. To prevent false tripping after startup, a large enough soft-start capacitor must be used to allow the output to get up to approximately 40% to 50% of the final value.

OPENLED Pin

The LT3791 provides an open-drain status pin, $\overline{\text{OPENLED}}$, which pulls low when the FB pin is above 1.15V and the voltage across $V_{(\text{ISP-ISN})}$ is less than 10mV. If the open LED clamp voltage is programmed correctly using the FB pin, then the FB pin should never exceed 1.1V when the LEDs are connected. Therefore, the only way for the FB pin to exceed 1.15V is for an open LED event to occur.

Soft-Start, Fault Function

Soft-start reduces the input power sources' surge currents by gradually increasing the controller's current limit (proportional to an internally buffered clamped equivalent of V_C). The soft-start interval is set by the soft-start capacitor selection according to the following equation

$$t_{\text{SS}} = \frac{1.2\text{V}}{14\mu\text{A}} \cdot C_{\text{SS}}$$

Make sure C_{SS} is large enough when there is loading during start-up.

The SS pin is also used as a fault timer. Once an open LED or a shorted LED fault is detected, a 1.4μA pull-down current source is activated. With a 500k pull-up resistor to V_{REF} on the SS pin, the LT3791 will latch off until the EN/UVLO pin is toggled. Without any resistor to V_{REF} the SS pin enters a hiccup mode operation. The 1.4μA pulls SS down until 0.2V is reached, at which point the 14μA pull-up current source turns on. If the fault condition hasn't been removed when SS reaches 1.75V, then the 1.4μA pull-down current source turns on again initiating a new cycle. This will continue until the fault is removed.

Loop Compensation

The LT3791 uses an internal transconductance error amplifier whose V_C output compensates the control loop. The external inductor, output capacitor and the compensation resistor and capacitor determine the loop stability.

The inductor and output capacitor are chosen based on performance, size and cost. The compensation resistor and capacitor at V_C are set to optimize control loop response and stability. For typical LED applications, a 10nF compensation capacitor at V_C is adequate, and a series resistor should always be used to increase the slew rate on the V_C pin to maintain tighter regulation of LED current during fast transients on the input supply of the converter.

APPLICATIONS INFORMATION

Power MOSFET Selections and Efficiency Considerations

The LT3791 requires four external N-channel power MOSFETs, two for the top switches (switch M1 and M4, shown in Figure 1) and two for the bottom switches (switch M2 and M3 shown in Figure 1). Important parameters for the power MOSFETs are the breakdown voltage, $V_{BR(DSS)}$, threshold voltage, $V_{GS(TH)}$, on-resistance, $R_{DS(ON)}$, reverse transfer capacitance, C_{RSS} , and maximum current, $I_{DS(MAX)}$.

The drive voltage is set by the 5V $INTV_{CC}$ supply. Consequently, logic-level threshold MOSFETs must be used in LT3791 applications. If the input voltage is expected to drop below the 5V, then sub-logic threshold MOSFETs should be considered.

In order to select the power MOSFETs, the power dissipated by the device must be known. For switch M1, the maximum power dissipation happens in boost operation, when it remains on all the time. Its maximum power dissipation at maximum output current is given by:

$$P_{M1(BOOST)} = \left(\frac{I_{LED} \cdot V_{OUT}}{V_{IN}} \right)^2 \cdot \rho_T \cdot R_{DS(ON)}$$

where ρ_T is a normalization factor (unity at 25°C) accounting for the significant variation in on-resistance with temperature, typically 0.4%/°C as shown in Figure 10. For a maximum junction temperature of 125°C, using a value of $\rho_T = 1.5$ is reasonable.

Switch M2 operates in buck operation as the synchronous rectifier. Its power dissipation at maximum output current is given by:

$$P_{M2(BUCK)} = \frac{V_{IN} - V_{OUT}}{V_{IN}} \cdot I_{LED}^2 \cdot \rho_T \cdot R_{DS(ON)}$$

Switch M3 operates in boost operation as the control switch. Its power dissipation at maximum current is given by:

$$P_{M3(BOOST)} = \frac{(V_{OUT} - V_{IN}) \cdot V_{OUT}}{V_{IN}^2} \cdot I_{LED}^2 \cdot \rho_T \cdot R_{DS(ON)} + k \cdot V_{OUT}^3 \cdot \frac{I_{LED}}{V_{IN}} \cdot C_{RSS} \cdot f$$

where C_{RSS} is usually specified by the MOSFET manufacturers. The constant k , which accounts for the loss caused by reverse-recovery current, is inversely proportional to the gate drive current and has an empirical value of 1.7.

For switch M4, the maximum power dissipation happens in boost operation, when its duty cycle is higher than 50%. Its maximum power dissipation at maximum output current is given by:

$$P_{M4(BOOST)} = \frac{V_{IN}}{V_{OUT}} \cdot \left(\frac{I_{LED} \cdot V_{OUT}}{V_{IN}} \right)^2 \cdot \rho_T \cdot R_{DS(ON)}$$

For the same output voltage and current, switch M1 has the highest power dissipation and switch M2 has the lowest power dissipation unless a short occurs at the output.

APPLICATIONS INFORMATION

From a known power dissipated in the power MOSFET, its junction temperature can be obtained using the following formula:

$$T_J = T_A + P \cdot R_{TH(JA)}$$

The $R_{TH(JA)}$ to be used in the equation normally includes the $R_{TH(JC)}$ for the device plus the thermal resistance from the case to the ambient temperature ($R_{TH(JC)}$). This value of T_J can then be compared to the original, assumed value used in the iterative calculation process.

Figure 10. Normalized $R_{DS(ON)}$ vs Temperature

Optional Schottky Diode (D3, D4) Selection

The Schottky diodes D3 and D4 shown in the Typical Applications section conduct during the dead time between the conduction of the power MOSFET switches. They are intended to prevent the body diode of synchronous switches M2 and M4 from turning on and storing charge during the dead time. In particular, D4 significantly reduces reverse-recovery current between switch M4 turn-off and switch M3 turn-on, which improves converter efficiency and reduces switch M3 voltage stress. In order for the

diode to be effective, the inductance between it and the synchronous switch must be as small as possible, mandating that these components be placed adjacently.

INTV_{CC} Regulator

An internal P-channel low dropout regulator produces 5V at the INTV_{CC} pin from the V_{IN} supply pin. INTV_{CC} powers the drivers and internal circuitry within the LT3791. The INTV_{CC} pin regulator can supply a peak current of 67mA and must be bypassed to ground with a minimum of 4.7μF ceramic capacitor or low ESR electrolytic capacitor. An additional 0.1μF ceramic capacitor placed directly adjacent to the INTV_{CC} and PGND IC pins is highly recommended. Good bypassing is necessary to supply the high transient current required by MOSFET gate drivers.

Higher input voltage applications in which large MOSFETs are being driven at high frequencies may cause the maximum junction temperature rating for the LT3791 to be exceeded. The system supply current is normally dominated by the gate charge current. Additional external loading of the INTV_{CC} also needs to be taken into account for the power dissipation calculations. Power dissipation for the IC in this case is $V_{IN} \cdot I_{INTVCC}$, and overall efficiency is lowered. The junction temperature can be estimated by using the equations given

$$T_J = T_A + (P_D \cdot \theta_{JA})$$

where θ_{JA} (in °C/W) is the package thermal impedance.

For example, a typical application operating in continuous current operation might draw 24mA from a 24V supply:

$$T_J = 70^\circ\text{C} + 24\text{mA} \cdot 24\text{V} \cdot 28^\circ\text{C/W} = 86^\circ\text{C}$$

To prevent maximum junction temperature from being exceeded, the input supply current must be checked operating in continuous mode at maximum V_{IN}.

APPLICATIONS INFORMATION

Top Gate (TG) MOSFET Driver Supply (C1, D1, C2, D2)

The external bootstrap capacitors C1 and C2 connected to the BST1 and BST2 pins supply the gate drive voltage for the topside MOSFET switches M1 and M4. When the top MOSFET switch M1 turns on, the switch node SW1 rises to V_{IN} and the BST1 pin rises to approximately $V_{IN} + INTV_{CC}$. When the bottom MOSFET switch M2 turns on, the switch node SW1 drops low and the bootstrap capacitor C1 is charged through D1 from $INTV_{CC}$. When the bottom MOSFET switch M3 turns on, the switch node SW2 drops low and the bootstrap capacitor C2 is charged through D2 from $INTV_{CC}$. The bootstrap capacitors C1 and C2 need to store about 100 times the gate charge required by the top MOSFET switch M1 and M4. In most applications a 0.1 μ F to 0.47 μ F, X5R or X7R ceramic capacitor is adequate.

Efficiency Considerations

The power efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Although all dissipative elements in circuits produce losses, four main sources account for most of the losses in LT3791 circuits:

1. DC I^2R losses. These arise from the resistances of the MOSFETs, sensing resistor, inductor and PC board traces and cause the efficiency to drop at high output currents.
2. Transition loss. This loss arises from the brief amount of time switch M1 or switch M3 spends in the saturated region during switch node transitions. It depends upon the input voltage, load current, driver strength and MOSFET capacitance, among other factors. The loss is significant at input voltages above 20V and can be estimated from:

$$\text{Transition Loss} \approx 2.7 \cdot V_{IN}^2 \cdot I_{OUT} \cdot C_{RSS} \cdot f$$
 where C_{RSS} is the reverse-transfer capacitance.
3. $INTV_{CC}$ current. This is the sum of the MOSFET driver and control currents.
4. C_{IN} and C_{OUT} loss. The input capacitor has the difficult job of filtering the large RMS input current to the regulator in buck operation. The output capacitor has the difficult job of filtering the large RMS output current in boost operation. Both C_{IN} and C_{OUT} are required to have low ESR to minimize the AC I^2R loss and sufficient capacitance to prevent the RMS current from causing additional upstream losses in fuses or batteries.
5. Other losses. Schottky diode D3 and D4 are responsible for conduction losses during dead time and light load conduction periods. Inductor core loss occurs predominately at light loads. Switch M3 causes reverse recovery current loss in boost operation.

When making adjustments to improve efficiency, the input current is the best indicator of changes in efficiency. If you make a change and the input current decreases, then the efficiency has increased. If there is no change in the input current, then there is no change in efficiency.

APPLICATIONS INFORMATION

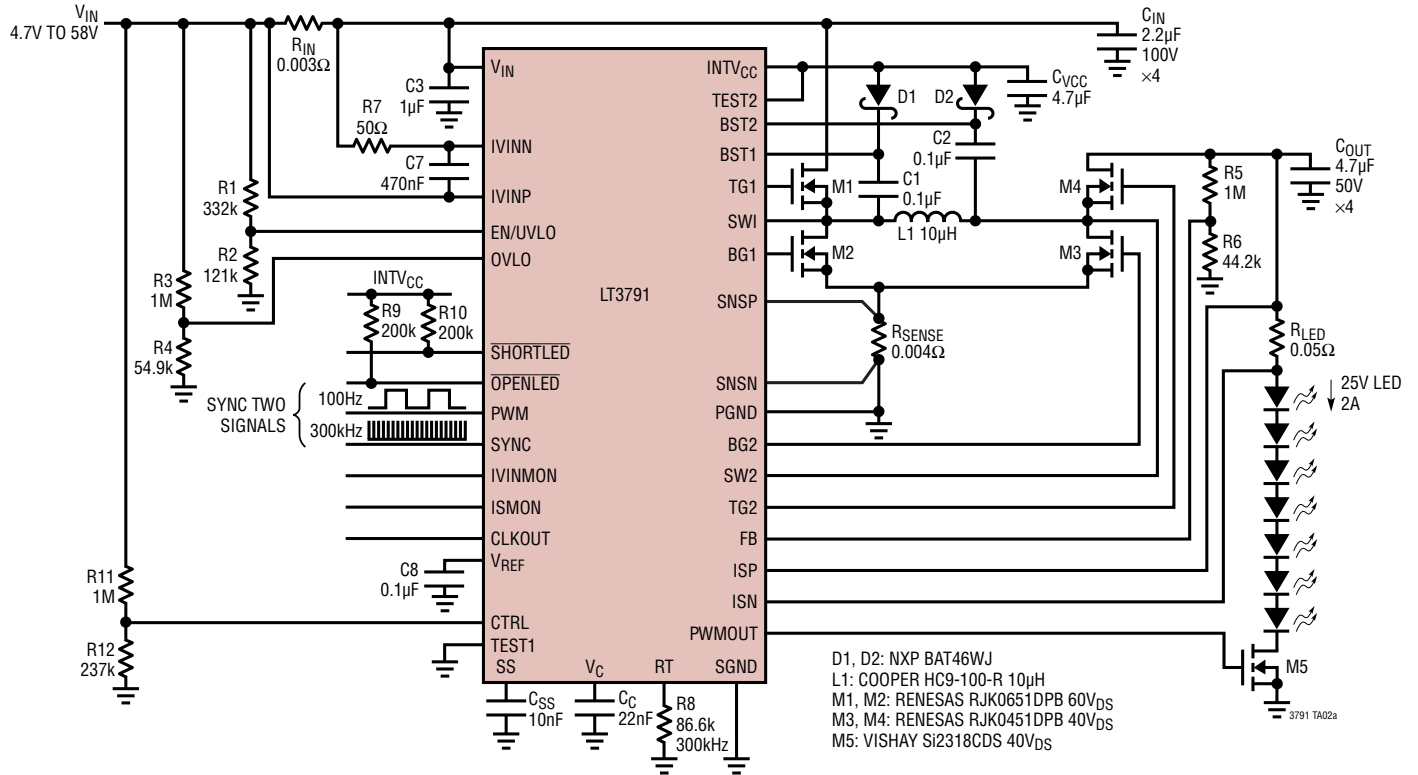

PC Board Layout Checklist

The basic PC board layout requires a dedicated ground plane layer. Also, for high current, a multilayer board provides heat sinking for power components.

- The PGND ground plane layer should not have any traces and it should be as close as possible to the layer with power MOSFETs.
- Place C_{IN} , switch M1, switch M2 and D1 in one compact area. Place C_{OUT} , switch M3, switch M4 and D2 in one compact area.
- Use immediate vias to connect the components (including the LT3791's SGND and PGND pins) to the ground plane. Use several large vias for each power component.
- Use planes for V_{IN} and V_{OUT} to maintain good voltage filtering and to keep power losses low.
- Flood all unused areas on all layers with copper. Flooding with copper will reduce the temperature rise of power components. Connect the copper areas to any DC net (V_{IN} or PGND).
- Separate the signal and power grounds. All small-signal components should return to the SGND pin at one point, which is then tied to the PGND pin close to the sources of switch M2 and switch M3.
- Place switch M2 and switch M3 as close to the controller as possible, keeping the PGND, BG and SW traces short.
- Keep the high dV/dT SW1, SW2, BST1, BST2, TG1 and TG2 nodes away from sensitive small-signal nodes.
- The path formed by switch M1, switch M2, D1 and the C_{IN} capacitor should have short leads and PC trace lengths. The path formed by switch M3, switch M4, D2 and the C_{OUT} capacitor also should have short leads and PC trace lengths.
- The output capacitor (–) terminals should be connected as close as possible to the (–) terminals of the input capacitor.
- Connect the top driver bootstrap capacitor, C1, closely to the BST1 and SW1 pins. Connect the top driver bootstrap capacitor, C2, closely to the BST2 and SW2 pins.
- Connect the input capacitors, C_{IN} , and output capacitors, C_{OUT} , closely to the power MOSFETs. These capacitors carry the MOSFET AC current in boost and buck operation.
- Route SNSN and SNSP leads together with minimum PC trace spacing. Avoid sense lines pass through noisy areas, such as switch nodes. Ensure accurate current sensing with Kelvin connections at the SENSE resistor.
- Connect the V_C pin compensation network close to the IC, between V_C and the signal ground pins. The capacitor helps to filter the effects of PCB noise and output voltage ripple voltage from the compensation loop.
- Connect the $INTV_{CC}$ bypass capacitor, C_{VCC} , close to the IC, between the $INTV_{CC}$ and the power ground pins. This capacitor carries the MOSFET drivers' current peaks. An additional 0.1 μF ceramic capacitor placed immediately next to the $INTV_{CC}$ and PGND pins can help improve noise performance substantially.

LT3756/LT3756-1 LT3756-2	High Side 100V, 1MHz LED Controller with True Color 3000:1 PWM Dimming	V_{IN} : 6V to 100V, V_{OUT} Range: 5V to 100V, 3000:1 True Color PWM, Analog, $I_{SD} < 1\mu A$, 3mm × 3mm QFN-16, MSOP-16E Packages
LT3596	60V, 300mA Step-Down LED Driver	V_{IN} : 6V to 60V, V_{OUT} Range: 5V to 55V, 10000:1 True Color PWM, Analog, $I_{SD} < 1\mu A$, 5mm × 8mm QFN-52 Package
LT3743	Synchronous Step-Down 20A LED Driver with Thee-State LED Current Control	V_{IN} : 5.5V to 36V, V_{OUT} Range: 5.5V to 35V, 3000:1 True Color PWM, Analog, $I_{SD} < 1\mu A$, 4mm × 5mm QFN-28, TSSOP-28E Packages
