DESCRIPTION

The APS11753 micropower Hall-effect switch ICs are qualified for low-voltage applications. These sensors are temperature-stable and suited for operation over extended junction temperature ranges up to 165°C. This family of Hall-effect switches provides contactless control of a push-pull output, which actuates in response to a magnetic field applied to the branded package face. Additionally, the micropower logic allows ultra-low power consumption and operation from 2.2 to 5.5 V.

These devices are equipped with chopper stabilization, which reduces the residual offset normally caused by device overmolding, temperature dependencies, and thermal stress, allowing superior high-temperature performance.

The APS11753 is offered in package type MD-3, a standard 3-pin SOT23-3 surface-mount package. The package is lead (Pb) free.

FUNCTIONAL DESCRIPTION

Operation

The APS11753 is an integrated Hall-effect sensor ICs with a switch output. The output is a push-pull configuration that actuates in response to a magnetic field applied to the branded package face (Figure 4). The devices are offered in package with a 3-pin surface-mount configuration. See the Selection Guide for a complete list of available options.

Unipolar South Pole: The unipolar output of these devices is actuated when a south polarity magnetic field perpendicular to the Hall element exceeds the operate point threshold, B_{OPS} (see Figure 4 Panels C and F). When B_{OPS} is exceeded, the APS11753 output turns on (goes low). When the magnetic field is removed or reduced below the release point, B_{RPS} , the device outputs return to their original state.

Unipolar North Pole: The unipolar output of these devices is actuated when a north polarity magnetic field perpendicular to the Hall element exceeds the operate point threshold, B_{OPN} (see Figure 4 Panels A and D). When B_{OPN} is exceeded, the APS1173

output turns on (goes low). When the magnetic field is removed or reduced below the release point, B_{RPN} , the device outputs return to their original state.

Omnipolar: The omnipolar operation of these devices allows actuation with either a north or a south polarity field. The APS11753 operates using the standard output polarity convention. Fields exceeding the operating points, B_{OPS} or B_{OPN} , will turn the output on (low). When the magnetic field is removed or reduced below the release point, B_{RPN} or B_{RPS} , the device output turns off (goes high).

The difference in the magnetic operate and release points is the hysteresis, B_{HYS} , of the device. This built-in hysteresis allows clean switching of the output even in the presence of external mechanical vibration and electrical noise.

Powering-on the device in the hysteresis range (less than B_{OP} and higher than B_{RP}) will give an output state of $V_{OUT(OFF)}$. In this case, the correct state is attained after the first excursion beyond B_{OP} or B_{RP} .

Low Average Power

The built-in micropower control periodically activates the Hall switch circuitry for a short period of time (t_{AWAKE}), and deactivates it for the remainder of the period (t_{PERIOD}). See Figure 6: Micropower Operation, for an example of the system timing. The short duration awake state allows for sensor stabilization prior

to sampling the Hall switch and latching the state on the output. The output is latched on the falling edge of the timing pulse and held in the last sampled state during the sleep period; updates to the output only occur on the falling edge of the timing pulse. The micropower control operates independently of the output driver state. At initial power-on, the APS11753 will sample a t_{AWAKE} cycle before the first t_{SLEEP} cycle (see Figure 6).

CHOPPER STABILIZATION

A limiting factor for switch point accuracy when using Hall-effect technology is the small signal voltage developed across the Hall plate. This voltage is proportionally small relative to the offset that can be produced at the output of the Hall sensor. This makes it difficult to process the signal and maintain an accurate, reliable output over the specified temperature and voltage range. Chopper Stabilization is a proven approach used to minimize Hall offset.

The Allegro technique, dynamic quadrature offset cancellation, removes key sources of the output drift induced by temperature and package stress. This offset reduction technique is based on a signal modulation-demodulation process. Figure 7: Model of Chopper Stabilization Circuit (Dynamic Offset Cancellation) illustrates how it is implemented.

The undesired offset signal is separated from the magnetically induced signal in the frequency domain through modulation. The

subsequent demodulation acts as a modulation process for the offset causing the magnetically induced signal to recover its original spectrum at baseband while the dc offset becomes a high frequency signal. Then, using a low-pass filter, the signal passes while the modulated DC offset is suppressed. Allegro's innovative chopper-stabilization technique uses a high frequency clock.

The high-frequency operation allows a greater sampling rate that produces higher accuracy, reduced jitter, and faster signal processing. Additionally, filtering is more effective and results in a lower noise analog signal at the sensor output. Devices such as the APS11753 that use this approach have an extremely stable quiescent Hall output voltage, are immune to thermal stress, and have precise recoverability after temperature cycling. This technique is made possible through the use of a BiCMOS process which allows the use of low offset and low noise amplifiers in combination with high-density logic and sample and hold circuits.
