

# High Noise Immunity, 3.3 V / 5 V Logic Gate Optocoupler

## FOD8001

### Description

The FOD8001 is a 3.3 V / 5 V high-speed logic gate optocoupler, which supports isolated communications allowing digital signals to communicate between systems without conducting ground loops or hazardous voltages. It utilizes ON Semiconductor patented coplanar packaging technology, Optoplanar<sup>®</sup>, and optimized IC design to achieve high noise immunity, characterized by high common mode rejection and power supply rejection specifications.

This high-speed logic gate optocoupler, packaged in a compact 8-pin small outline package, consists of a high-speed AlGaAs LED driven by a CMOS buffer IC coupled to a CMOS detector IC. The detector IC comprises an integrated photodiode, a high-speed transimpedance amplifier and a voltage comparator with an output driver. The CMOS technology coupled to the high efficiency of the LED achieves low power consumption as well as very high speed (40ns propagation delay, 6ns pulse width distortion).

### Features

- High Noise Immunity characterized by Common Mode Rejection (CMR) and Power Supply Rejection (PSR) Specifications
  - ♦ 20 kV/μs Minimum Static CMR @ V<sub>cm</sub> = 1000 V
  - ♦ 25 kV/μs Typical Dynamic CMR @ V<sub>cm</sub> = 1500 V, 20 MBaud Rate
  - ♦ PSR in Excess of 10% of the Supply Voltages across Full Operating Bandwidth
- High Speed:
  - ♦ 25 Mbit/s Data Rate (NRZ)
  - ♦ 40 ns max. Propagation Delay
  - ♦ 6 ns max. Pulse Width Distortion
  - ♦ 20 ns max. Propagation Delay Skew
- 3.3 V and 5 V CMOS Compatibility
- Extended Industrial Temperate Range, -40°C to 105°C Temperature Range
- Safety and Regulatory Pending Approvals:
  - ♦ UL1577, 3750 VACRMS for 1 min.
  - ♦ IEC60747-5-2 (pending)

### Applications

- Industrial Fieldbus Communications
  - ♦ Profibus, DeviceNet, CAN, RS485
- Programmable Logic Control
- Isolated Data Acquisition System

6.  $t_{PSK}$  is equal to the magnitude of the worst case difference in  $t_{PHL}$  and/or  $t_{PLH}$  that will be seen between units at any given temperature within the recommended operating conditions.

7. Common mode transient immunity at output high is the maximum tolerable positive  $dV_{cm}/dt$  on the leading edge of the common mode impulse signal,  $V_{cm}$ , to assure that the output will remain high. Common mode transient immunity at output low is the maximum tolerable negative  $dV_{cm}/dt$  on the trailing edge of the common pulse signal,  $V_{cm}$ , to assure that the output will remain low.

8. Unloaded dynamic power dissipation is calculated as follows:  $C_{PD} \times V_{DD} \times f + I_{DD} \times V_{PD}$  where  $f$  is switched time in MHz.

## APPLICATION INFORMATION

Noise is defined as any unwanted signal that degrades or interferes with the operation of a system or circuit. Input–output noise rejection is a key characteristic of an optocoupler, and the performance specification for this noise rejection is called, “Common Mode Transient Immunity or Common Mode Rejection, CMR”. The CMR test configuration is presented in high speed optocoupler datasheets, which tests the optocoupler to a specified rate of interfering signal ( $dv/dt$ ), at a specified peak voltage ( $V_{cm}$ ).

This defined noise signal is applied to the test device while the coupler is a stable logic high or logic low state. This test procedure evaluates the interface device in a constant or static logic state. This type of CMR can be referred to as “**Static CMR**”. ON Semiconductor high speed optocouplers, which use an optically transparent, electrically conductive shield, and offer active totem pole logic output have static CMR in excess of 50 kV/ $\mu$ s at peak amplitudes of 1.5 kV to 2.0 kV.

**Dynamic Common Mode Rejection**

The noise susceptibility of an interface while it is actively transferring data is a common requirement in serial data communication. However, the static CMR specification is not adequate in quantifying the electrical noise susceptibility for optocouplers used in isolating high speed data transfer.

A serial data communication network’s noise performance is usually quantified as the number of bit errors per second or as a ratio of the number of bits transmitted in a specified time frame. This describes Bit Error Rate, BER. Test equipment that evaluates BER is called a Bit Error Rate Tester, BERT. When a BERT system is combined with a CMR tester, the active or dynamic noise rejection of an isolated interface can then be quantified. This type of CMR is thus defined as “**Dynamic CMR**”. Therefore, evaluating the common mode rejection while the optocoupler is switching at high speed represents a realistic approach to understand noise interference.

Test circuit functions were built to interface a commercial pseudo–random bit sequence (PRBS) generator and error detector with a pair of high speed optocouplers, FOD8001, connected in a loop–back configuration. With a 10 MBaud PRBS serial data stream, no error was detected until the common mode voltage rose above 2.5 kV with a  $dv/dt$  of 45 kV/ $\mu$ s. And increasing the data rate beyond 10 MBaud, the test was conducted at 20 MBaud, and no error was detected at  $dv/dt$  of 25 kV/ $\mu$ s at common mode voltage of 1.5 kV.

The test data for the dynamic CMR is comparable or better than the static CMR specifications found in the datasheet. These excellent noise rejection performances are results of the innovative circuit design and the patented coplanar assembly process.

**Power Supply Noise Rejection**

High levels of electrical noise can cause the optocoupler to register the incorrect logic state. The most commonly discussed noise signal is the common mode noise found between the input and output of the optocoupler. However, common mode noise is not the only path of noise into the input or output of the optocoupler. Due to the high gain and wide bandwidth of the transimpedance amplifier used for the photo detector circuits, power supply noise can cause the optocoupler to change state independent of the LED operation. Power supply noise is typically characterized as either random or periodic pulses with varying amplitudes and rates of rise and fall. The necessary tests have been conducted to understand the influence of the power supply noise and its effect of the proper operation of the FOD8001. The optocoupler under test offered power supply noise rejection in excess of 10% of the supply voltage for a frequency ranging from 100 kHz to 35 MHz, for logic high and logic low states.
