

MC74LVXT4051

Analog Multiplexer/ Demultiplexer

High-Performance Silicon-Gate CMOS

The MC74LVXT4051 utilizes silicon-gate CMOS technology to achieve fast propagation delays, low ON resistances, and low leakage currents. This analog multiplexer/demultiplexer controls analog voltages that may vary across the complete power supply range (from V_{CC} to V_{EE}).

The LVXT4051 is similar in pinout to the LVX8051, the HC4051A, and the metal-gate MC14051B. The Channel-Select inputs determine which one of the Analog Inputs/Outputs is to be connected, by means of an analog switch, to the Common Output/Input. When the Enable pin is HIGH, all analog switches are turned off.

The Channel-Select and Enable inputs are compatible with standard TTL levels. These inputs are over-voltage tolerant (OVT) for level translation from 6.0 V down to 3.0 V.

This device has been designed so the ON resistance (R_{ON}) is more linear over input voltage than the R_{ON} of metal-gate CMOS analog switches and High-Speed CMOS analog switches.

Features

- Select Pins Compatible with TTL Levels
- Fast Switching and Propagation Speeds
- Low Crosstalk Between Switches
- Analog Power Supply Range ($V_{CC} - V_{EE}$) = -3.0 V to +3.0 V
- Digital (Control) Power Supply Range ($V_{CC} - GND$) = 2.5 to 6.0 V
- Improved Linearity and Lower ON Resistance Than Metal-Gate, HSL, or VHC Counterparts
- Low Noise
- Designed to Operate on a Single Supply with $V_{EE} = GND$, or Using Split Supplies up to ± 3.0 V
- Break-Before-Make Circuitry
- These Devices are Pb-Free and are RoHS Compliant

APPLICATIONS INFORMATION

The Channel Select and Enable control pins should be at V_{CC} or GND logic levels. V_{CC} being recognized as a logic high and GND being recognized as a logic low. In this example:

$$\begin{aligned} V_{CC} &= +5 \text{ V} = \text{logic high} \\ \text{GND} &= 0 \text{ V} = \text{logic low} \end{aligned}$$

The maximum analog voltage swing is determined by the supply voltages V_{CC} and V_{EE} . The positive peak analog voltage should not exceed V_{CC} . Similarly, the negative peak analog voltage should not go below V_{EE} . In this example, the difference between V_{CC} and V_{EE} is five volts. Therefore, using the configuration of Figure 20, a maximum analog signal of five volts peak-to-peak can be controlled. Unused analog inputs/outputs may be left floating (i.e., not connected). However, tying unused analog inputs and

outputs to V_{CC} or GND through a low value resistor helps minimize crosstalk and feedthrough noise that may be picked up by an unused switch.

Although used here, balanced supplies are not a requirement. The only constraints on the power supplies are that:

$$\begin{aligned} V_{EE} - \text{GND} &= 0 \text{ to } -6 \text{ volts} \\ V_{CC} - \text{GND} &= 2.5 \text{ to } 6 \text{ volts} \\ V_{CC} - V_{EE} &= 2.5 \text{ to } 6 \text{ volts} \\ &\text{and } V_{EE} \leq \text{GND} \end{aligned}$$

When voltage transients above V_{CC} and/or below V_{EE} are anticipated on the analog channels, external Germanium or Schottky diodes (D_x) are recommended as shown in Figure 21. These diodes should be able to absorb the maximum anticipated current surges during clipping.

Figure 19. Application Example
