By AIM, AY1 and AX1 registers, the setting-up of increment operation /non-operation for the X-address counter and the Y-address counter every write access of every read access to the Graphic Display RAM is possible.

In setting to this control register, the increment operation of address can be made without setting successive addresses for writing data or for reading data to the Graphic Display RAM from MPU.

After setting this register be sure to set the X and Y Address Register.

Because it is not assuring the data of X and Y Address Register after setting increment Control Register.

The increment control of X and Y address by AIM, AY1 and AX1 registers is as follows.

ALM	SELECTION OF INCREMENT TIMING	REFERENCE
0	When writing to Graphic Display RAM or reading from Graphic Display RAM	<1>
1	Only when writing to Graphic Display RAM (read modify)	<2>

2.5 Function Description

2.5.1 MPU Interface

2.5.1-1 Interface Type Selection

The LH155BA performs data transfer via the 8-bit data bus or the serial data input (the SDA or SCL pin). The parallel or serial interface is selected by setting the polarity of the P/S pin to “H” or “L”. When selecting serial interface, data-reading cannot be performed.

but only data writing can.

P/S	I/F type	CSB	RS	RDB	WRB	M86	SDA	SCL	Data
H	Parallel	CSB	RS	RDB	WRB	M86	-	-	D0 to D7
L	Serial	CSB	RS	-	-	-	SDA	SCL	-

2.5.1-2 Parallel input

The LH155BA allows parallel data transfer by connecting the data bus to an 8-bit MPU if the parallel interface is selected with the P/S pin.

For this 8-bit MPU, the 80-family or 68-family MPU type interface can be selected with the M86 pin.

M86	MPU type	CSB	RS	RDB	WRB	Data
L	80-family MPU	CSB	RS	RDB	WRB	D0 to D7

2.5.1-3 Data identification

The LH155BA identifies the data types over the 8-bit data bus by combinations of RS,RDB and WRB signals.

RS	80-family		FUNCTION
	WRB	RDB	
1	0	1	Read internal register
1	1	0	Write internal register
0	0	1	Read display data
0	1	0	Write display data

2.5.1-4 Serial interface

The serial interface for the LH155BA is enabled to accept the SDA and SCL inputs when the chip is selected. If the chip is not selected, the internal shift register and counter are reset to the initial state.

The data input is taken in the order of D7...D1, and D0 starting with the serial data input SDA when the serial clock (SCL) rises. At the leading edge of the 8th serial clock, the serial data is converted into 8-bit parallel data and then processed according to its type.

The serial data input (SDA) is identified with input at the RS pin.

The serial clock input (SCL) must be set to "L" if it is not accessed. After 8-bit data transfer is finished, it must be also set to "L".

For the SDA and SCL signals, sufficient care must be taken for external noise. In order to prevent continuous error recognition of transferred data occurring from external noise, the chip selected must be released (CSB="H") whenever 8-bit data transfer is finished.

2.5.2 Access to Display RAM and Internal Register

The LH155BA makes access to Display RAM, and internal register by data bus D0~D7, chip select CSB is at "H", it is in non-selective state and cannot make access to Display RAM and internal registers, in making access to them, set CSB to "L".

The access to either Display RAM or internal registers can be shifted by RS input.

RS="L": Display RAM data

RS="H": Internal command register

The data of 8-bit data bus D0~D7 are written by write operation after address setting through MPU. The timing of Write is at the rising of WRB for 80 family MPU and at the falling of E for 68 family MPU respectively.

Write is internally processed by placing intermediately the bus holder in the internal data bus. In case of writing data from MPU, the data are temporally held in the bus holder before they are written by the time of the next cycle. Since the Read sequence of Display RAM data is limited, note that when Address Set is made, the designated address data are not output to Read Command immediately after the Address Set, but are output when the second data Read, resulting in requiring dummy Read one time. Dummy Read is always required one time after Address Set

Data Read Operation

Data Write Operation

2.5.3 Read of internal Register

The LH155BA reads not only Display RAM, but also the internal registers.

Addresses for Read (0.2~E[hex]) are allotted to each internal register. In reading the internal registers, the addresses of internal registers allotted to read are written in the register Read and then are read.

2.5.4 Display Mode

The LH155BA have 3 Display modes.

One is for Graphic Display mode and one is for Segment display mode and the other is for icon Display. 3 mode are independent of each other, so each mode can function alone. That can drive a minimum circuit each display mode. A suitable mode for lower current consumption is selectable.

2.5.4-1 Graphic Display Mode

This mode enable 64x128 Bits - in SRAM and 64 command x 128 segment output terminal.

Graphic Display's Memory map is below.

When Stand-by mode and Sleep mode, power supply circuit is stopped and output terminal is specified VSS level.

The Memory for Graphic Display is accessed by 8 bits at one time.

X address is from 00H to 0FH and Y address is from 00H to 3FH. (See table A)

2.5.5 Display Starting Line Register

This register is for determining display start line (usually the most upper line)

Corresponding to COM0 in case of display the Display data RAM.

The register is also used in picture-scrolling.

The 6-bit display starting address is set in this register by display starting-line setting command.

The register are preset every timing of FLM signal variation in the display line counter. The line counter counts up being synchronized with LP input and generates line addressed which read out sequentially 128-bit data from Display RAM to LCD driver circuit.

2.5.6 Addressing of Display RAM

Display RAM consists of 128 x 64 bit memory, and makes access in 8 bit unit to an address specified by X address and Y address from MPU.

The address, X and Y are possible to be set up so that can increment automatically with the address control register. The increment is made every time Display RAM is read or written from MPU.

Though the X direction side is selected by X address while the Y direction side by Y address, 10H-FFH in the X address are inhibited and do not have the X address set in these addresses.

In the Y direction side, the 128-bit display data are internally read the display data latch circuit at the rising of LP every one line cycle, and are output from the display data latch circuit at the falling of LP.

43H-FFH in the Y address are inhibited and do not have the Y address set in these addresses.

When FLM signals being output in one frame cycle are at "H", the value in the display starting line register are preset in the line counter and the line counter counts up at the falling of LP signals.

The display line address counter is synchronized with each timing signal of the LCD system to operate and is independent of address counters, X and Y.

Segment Output	SEG0	SEG1	SEG2	SEG3	SEG4	SEG5	SEG6	SEG7	SEG8	SEG9	SEG10	SEG11	SEG12	SEG13	SEG14	SEG15	...	SEG120	SEG121	SEG122	SEG123	SEG124	SEG125	SEG126	SEG127
----------------	------	------	------	------	------	------	------	------	------	------	-------	-------	-------	-------	-------	-------	-----	--------	--------	--------	--------	--------	--------	--------	--------

2.5.9 Display Timing Generator

The display timing generator generates a timing clock necessary for internal operation and timing pulses (LP, FLM, and M) by inputting the original oscillating clock CK or by the oscillating circuit of OSC1 and OSC0.

By setting up Master/Slave mode(M/S), the state of timing pulse pins and the timing generator changes.

2.5.10 Signal Generation to Display Line Counter, and Display Data Latching Circuit

Both the clock to the line counter and latching signals to display data latching circuit from the display clock (LP) are generated.

Synchronized with the display clock, the line addresses of Display RAM are generated and 128-bit display data are latched to display-data latching circuit to output to the LCD driver circuit (SEG output).

2.5.11 Generation of the Alternated Signal (M) and the Synchronous Signal (FLM)

LCD alternated signal (M) and synchronous signal (FLM) are generated by the display clock (LP). The FLM generates alternated drive waveform to the LCD driver circuit. Normally the FLM generates alternated driver drive waveform every frame unit.

(M-signal level is reversed every one frame).

But by setting up data (n-1) in an n-line reverse register and n-line alternated command (NLIN) at “H”, n-line reverse waveform is generated.

When the LH155BA is used in multi-chip, the signals of LP, FLM, and M must be sent from Master side in the Slave operation.

2.5.12 Display Data Latching Circuit

Display Data Latching Circuit temporary latches display data that is output display data to LCD driver circuit from Display RAM every one common period. Normal display /reverse display, display ON/OFF, and display all on command are operated by controlling data in the latch. And no data within Display RAM changes.
