

# OPTIREG™ Linear TLE42994V33

## 3.3 V low drop fixed voltage regulator

## 1 Overview

### Features

- Output voltage  $3.3\text{ V} \pm 2\%$
- Output current up to 150 mA
- Extreme low current consumption in ON state
- Enable function: Below 1  $\mu\text{A}$  current consumption in OFF state
- Early warning
- Power-on and undervoltage reset with programmable delay time
- Reset low down to  $V_Q = 1\text{ V}$
- Adjustable reset threshold
- Very low dropout voltage
- Output current limitation
- Reverse polarity protection
- Overtemperature protection
- Suitable for use in automotive electronics
- Wide temperature range from  $-40^\circ\text{C}$  up to  $150^\circ\text{C}$
- Input voltage range from 4.4 V to 45 V
- Green Product (RoHS compliant)

### Potential applications

General automotive applications.

### Product validation

Qualified for automotive applications. Product validation according to AEC-Q100/101.

### Description

The TLE42994V33 is a monolithic integrated low dropout voltage regulator, especially designed for automotive applications that need to be in ON state during the car's engine is turned off. An input voltage up to 45 V is regulated to an output voltage of 3.3 V. The component is able to drive loads up to 150 mA. It is short-circuit protected by the implemented current limitation and has an integrated overtemperature shutdown. A

## Overview

reset signal is generated for an output voltage  $V_{Q,rt}$  of typically 3.10 V. This threshold can be decreased by an external resistor divider. The power-on reset delay time can be programmed by the external delay capacitor. The additional sense comparator provides an early warning function: Any voltage (e.g. the input voltage) can be monitored, an undervoltage condition is indicated by setting the comparator's output to low. Additionally, an enable function permitting enabling/disabling the regulator is also included. In case the regulator is disabled it consumes less current than 1  $\mu$ A.

## Dimensioning information on external components

The input capacitor  $C_I$  is recommended for compensation of line influences. The output capacitor  $C_Q$  is necessary for the stability of the control loop.

## Circuit description

The control amplifier compares a reference voltage to a voltage that is proportional to the output voltage and drives the base of the series transistor via a buffer. Saturation control as a function of the load current prevents any oversaturation of the power element. The component also has a number of internal circuits for protection against:

- Overload
- Overtemperature
- Reverse polarity

| Type          | Package                | Marking  |
|---------------|------------------------|----------|

| Storage temperature                        | $T_{stg}$             | -50    | –    | 150  | °C   | –                                                      | P_4.1.5 |
| ESD absorption                             |                       |        |      |      |      |                                                        |         |
| ESD absorption                             | $V_{ESD,HBM}$         | -2     | –    | 2    | kV   | Human body model (HBM) <sup>2)</sup>                   | P_4.1.6 |
| ESD absorption                             | $V_{ESD,CDM}$         | -500   | –    | 500  | V    | Charge device model (CDM) <sup>3)</sup>                | P_4.1.7 |
| ESD absorption                             | $V_{ESD,CDM}$         | -750   | –    | 750  | V    | Charge device model (CDM) <sup>3)</sup> at corner pins | P_4.1.8 |

1) Not subject to production test, specified by design

2) ESD susceptibility human body model “HBM” according to AEC-Q100-002 - JESD22-A114

3) ESD susceptibility charged device model “CDM” according to ESDA STM5.3.1

### Notes

- Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
- Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as “outside” normal operating range. Protection functions are not designed for continuous repetitive operation.

1) Not subject to production test, specified by design

2) Specified  $R_{thJA}$  value is according to Jedec JESD51-2,-5,-7 at natural convection on FR4 2s2p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm<sup>3</sup> board with 2 inner copper layers (2 x 70μm Cu, 2 x 35μm Cu). Where applicable a thermal via array under the exposed pad contacted the first inner copper layer.

3) Specified  $R_{thJA}$  value is according to JEDEC JESD 51-3 at natural convection on FR4 1s0p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm<sup>3</sup> board with 1 copper layer (1 x 70μm Cu).

## 5 Block description and electrical characteristics

### 5.1 Voltage regulator

The output voltage  $V_Q$  is controlled by comparing a portion of it to an internal reference and driving a PNP pass transistor accordingly. The control loop stability depends on the output capacitor  $C_Q$ , the load current, the chip temperature and the poles/zeros introduced by the integrated circuit. To ensure stable operation, the output capacitor's capacitance and its equivalent series resistor ESR requirements given in the table **"Functional range" on Page 9** have to be maintained. For details see also the typical performance graph **"Output Capacitor Series Resistor ESR( $C_Q$ ) versus Output Current  $I_Q$ " on Page 14**. As the output capacitor also has to buffer load steps it should be sized according to the application's needs.

An input capacitor  $C_I$  is strongly recommended to compensate line influences. Connect the capacitors close to the component's terminals.

A protection circuitry prevents the IC as well as the application from destruction in case of catastrophic events. These safeguards contain an output current limitation, a reverse polarity protection as well as a thermal shutdown in case of overtemperature.

To avoid excessive power dissipation that could never be handled by the pass element and the package, the maximum output current is decreased at input voltages above  $V_I = 22$  V.

The overtemperature shutdown circuit prevents the IC from immediate destruction under fault conditions (e.g. output continuously short-circuited) by switching off the power stage. After the chip has cooled down, the regulator restarts. This leads to an oscillatory behavior of the output voltage until the fault is removed. However, junction temperatures above 150 °C are outside the maximum ratings and therefore significantly reduce the IC's lifetime.

The TLE42994V33 allows a negative supply voltage. In this fault condition, small currents are flowing into the IC, increasing its junction temperature. This has to be considered for the thermal design, respecting that the thermal protection circuit is not operating during reverse polarity conditions.

## Block description and electrical characteristics

### 5.6 Reset function

The reset function provides several features:

#### Output undervoltage reset:

An output undervoltage condition is indicated by setting the Reset Output RO to “low”. This signal might be used to reset a microcontroller during low supply voltage.

#### Power-on reset delay time:

The power-on reset delay time  $t_{rd}$  allows a microcontroller and oscillator to start up. This delay time is the time frame from exceeding the reset switching threshold  $V_{RT}$  until the reset is released by switching the reset output “RO” from “low” to “high”. The power-on reset delay time  $t_{rd}$  is defined by an external delay capacitor  $C_D$  connected to pin D charged by the delay capacitor charge current  $I_{D,ch}$  starting from  $V_D = 0$  V.

If the application needs a power-on reset delay time  $t_{rd}$  different from the value given in **Power-on reset delay time**, the delay capacitor's value can be derived from the specified values in **Power-on reset delay time** and the desired power-on delay time:

(5.1)

$$C_D = \frac{t_{rd, new}}{t_{rd}} \times 100 \text{ nF}$$

with

- $C_D$ : capacitance of the delay capacitor to be chosen
- $t_{rd, new}$ : desired power-on reset delay time
- $t_{rd}$ : power-on reset delay time specified in this datasheet

For a precise calculation also take the delay capacitor's tolerance into consideration.

#### Reset reaction time:

The reset reaction time avoids that short undervoltage spikes trigger an unwanted reset “low” signal. The reset reaction time  $t_{rr}$  considers the internal reaction time  $t_{rr, int}$  and the discharge time  $t_{rr, d}$  defined by the external delay capacitor  $C_D$  (see typical performance graph for details). Hence, the total reset reaction time becomes:

(5.2)

$$t_{rr} = t_{rd, int} + t_{rr, d}$$

with

- $t_{rr}$ : reset reaction time
- $t_{rr, int}$ : internal reset reaction time
- $t_{rr, d}$ : reset discharge

#### Optional reset output pull-up resistor $R_{RO, ext}$ :

The Reset Output RO is an open collector output with an integrated pull-up resistor. If needed, an external pull-up resistor to the output Q can be added. In **Table 7 “Electrical characteristics reset function” on Page 20** a minimum value for the external resistor  $R_{RO, ext}$  is given.

## Block description and electrical characteristics

### Reset adjust function

The undervoltage reset switching threshold can be adjusted according to the application's needs by connecting an external voltage divider ( $R_{ADJ1}$ ,  $R_{ADJ2}$ ) at pin RADJ. For selecting the default threshold connect pin RADJ to GND.

When dimensioning the voltage divider, take into consideration that there will be an additional current constantly flowing through the resistors.

With a voltage divider connected, the reset switching threshold  $V_{RT,new}$  is calculated as follows:

(5.3)

$$V_{RT,new} = \frac{R_{ADJ,1} + R_{ADJ,2}}{R_{ADJ,2}} \times V_{RADJ,th}$$

with

- $V_{RT,new}$ : the desired new reset switching threshold
- $R_{ADJ1}$ ,  $R_{ADJ2}$ : resistors of the external voltage divider
- $V_{RADJ,th}$ : reset adjust switching threshold given in **Table 7 “Electrical characteristics reset function” on Page 20**

**Figure 5** Block diagram reset function

## Application information

## 6 Application information

*Note: The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.*

### 6.1 Application diagram

**Figure 8 Application diagram with selecting default reset thresholds**

**Figure 9 Application diagram with reset thresholds adjustment**

## Application information

### 6.2 Selection of external components

#### 6.2.1 Input pin

The typical input circuitry for a linear voltage regulator is shown in the application diagram above.

A ceramic capacitor at the input, in the range of 100 nF to 470 nF, is recommended to filter out the high frequency disturbances imposed by the line e.g. ISO pulses 3a/b. This capacitor must be placed very close to the input pin of the linear voltage regulator on the PCB.

An aluminum electrolytic capacitor in the range of 10  $\mu$ F to 470  $\mu$ F is recommended as an input buffer to smooth out high energy pulses, such as ISO pulse 2a. This capacitor should be placed close to the input pin of the linear voltage regulator on the PCB.

An overvoltage suppressor diode can be used to further suppress any high voltage beyond the maximum rating of the linear voltage regulator and protect the device against any damage due to over-voltage.

The external components at the input are not mandatory for the operation of the voltage regulator, but they are recommended in case of possible external disturbances.

#### 6.2.2 Output pin

An output capacitor is mandatory for the stability of linear voltage regulators.

The requirement to the output capacitor is given in **“Functional range” on Page 9**. The graph shows the stable operation range of the device. **“Output Capacitor Series Resistor ESR(CQ) versus Output Current IQ” on Page 14**

TLE42994 is designed to be stable with extremely low ESR capacitors. According to the automotive environment, ceramic capacitors with X5R or X7R dielectrics are recommended.

The output capacitor should be placed as close as possible to the regulator's output and GND pins and on the same side of the PCB as the regulator itself.

In case of rapid transients of input voltage or load current, the capacitance should be dimensioned in accordance and verified in the real application that the output stability requirements are fulfilled.

## Application information

### 6.3 Thermal considerations

Knowing the input voltage, the output voltage and the load profile of the application, the total power dissipation can be calculated:

(6.1)

$$P_D = (V_I - V_Q) \times I_Q + V_I \times I_q$$

with

- $P_D$ : continuous power dissipation
- $V_I$ : input voltage
- $V_Q$ : output voltage
- $I_Q$ : output current
- $I_q$ : quiescent current

The maximum acceptable thermal resistance  $R_{thJA}$  can then be calculated:

(6.2)

$$R_{thJA, \max} = \frac{T_{j, \max} - T_a}{P_D}$$

with

- $T_{j, \max}$ : maximum allowed junction temperature
- $T_a$ : ambient temperature

Based on the above calculation the proper PCB type and the necessary heat sink area can be determined with reference to the specification in **“Thermal resistance” on Page 10**.

### Example

Application conditions:

$$V_I = 13.5 \text{ V}$$

$$V_Q = 3.3 \text{ V}$$

$$I_Q = 50 \text{ mA}$$

$$T_a = 105^\circ\text{C}$$

## Application information

Calculation of  $R_{thJA,max}$ :

$$\begin{aligned} P_D &= (V_I - V_Q) \cdot I_Q + V_I \cdot I_q \\ &= (13.5 \text{ V} - 3.3 \text{ V}) \cdot 50 \text{ mA} + 13.5 \text{ V} \cdot 2 \text{ mA} \\ &= 0.510 \text{ W} + 0.027 \text{ W} \\ &= 0.537 \text{ W} \\ R_{thJA,max} &= (T_{j,max} - T_a) / P_D \\ &= (150^\circ\text{C} - 105^\circ\text{C}) / 0.537 \text{ W} \\ &= 83.8 \text{ K/W} \end{aligned}$$

As a result, the PCB design must ensure a thermal resistance  $R_{thJA}$  lower than 55.3 K/W. By considering TLE42994E (PG-SSOP-14 EP package) and according to **“Thermal resistance” on Page 10**, at least 600 mm<sup>2</sup> heatsink area is needed on the FR4 1s0p PCB, or the FR4 2s2p board can be used.

## 6.4 Reverse polarity protection

TLE42994 is self protected against reverse polarity faults and allows negative supply voltage. External reverse polarity diode is not needed. However, the absolute maximum ratings of the device as specified in **“Absolute maximum ratings” on Page 8** must be kept.

The reverse voltage causes several small currents to flow into the IC hence increasing its junction temperature. As the thermal shut down circuitry does not work in the reverse polarity condition, designers have to consider this in their thermal design.

## **Package information**

### **Green Product (RoHS compliant)**

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).
