

GENERAL DESCRIPTION

The SGM6014 is a high efficiency monolithic synchronous step-down regulator using 1.4MHz constant frequency, current mode architecture. The device is available in an adjustable version. It is ideal for portable equipment requiring very high current up to 2A from single-cell Li-Ion batteries while still achieving over 95% efficiency during peak load conditions. The SGM6014 can enter pulse frequency modulation (PFM) (low I_Q) mode with typically 55 μ A quiescent current for highest light load efficiency to maximize battery life.

The SGM6014 also can run at 100% duty cycle for low dropout operation, extending battery life in portable systems while light load operation provides very low output ripple for noise sensitive applications. It can supply up to 2A output load current from a 2.5V to 5.5V input voltage and the output voltage can be regulated as low as 1.2V. The high switching frequency (1.4MHz) minimizes the size of external components while keeping switching losses low. The internal slope compensation setting allows the device to operate with smaller inductor values to optimize size and provide efficient operation.

SGM6014 is available in both adjustable and 3.3V fixed output voltage versions; in the Green TDFN-3 $\times$ 3-10L package. It is rated over the -40 $^{\circ}$ C to +85 $^{\circ}$ C temperature range.

FEATURES

- High Efficiency: Up to 95%
- 2.5V to 5.5V Input Voltage Range
- 1.4MHz Constant Frequency Operation
- 2A Output Current
- 3.3V Fixed and Adjustable Output Voltages
- 100% Duty Cycle for Lowest Dropout
- Less than 2 μ A Shutdown Current
- Low Quiescent Current: 55 μ A in PFM Mode
- Low $R_{DS(ON)}$ Internal Switches: 0.135 Ω
- Allows Use of Ceramic Capacitors
- Current Mode Control for Excellent Line and Load Transient Response
- Internal Soft-Start Protection
- Short Circuit and Thermal Protection
- -40 $^{\circ}$ C to +85 $^{\circ}$ C Operating Temperature Range
- Available in Green TDFN-3 $\times$ 3-10L Package

APPLICATIONS

PDA, Pocket PC and Smart Phones
 USB Powered Modems
 CPUs and DSPs
 PC Cards and Notebooks
 Cellular Phones
 Digital Cameras
 DSP Core Supplies
 Portable Instruments

PACKAGE/ORDERING INFORMATION

MODEL	V _{OUT} (V)	PACKAGE DESCRIPTION	SPECIFIED TEMPERATURE RANGE	ORDERING NUMBER	PACKAGE MARKING	PACKING OPTION
SGM6014	Adjustable	TDFN-3×3-10L	-40°C to +85°C	SGM6014-ADJYTD10G/TR	SGM SHDD XXXXX	Tape and Reel, 3000
	3.3	TDFN-3×3-10L	-40°C to +85°C	SGM6014-3.3YTD10G/TR	SGM SIBD XXXXX	Tape and Reel, 3000

NOTE: XXXXX = Date Code and Vendor Code.

Green (RoHS & HSF): SG Micro Corp defines "Green" to mean Pb-Free (RoHS compatible) and free of halogen substances. If you have additional comments or questions, please contact your SGMICRO representative directly.

ABSOLUTE MAXIMUM RATINGS

Input Supply Voltage..... -0.3V to 6V
 EN Voltage..... -0.3V to V_{IN} + 0.3V
 FB/OUT, SW Voltages..... -0.3V to V_{IN} + 0.3V
 Power Dissipation, P_D @ T_A = +25°C
 TDFN-3×3-10L..... 2.2W
 Package Thermal Resistance
 TDFN-3×3-10L, θ_{JA}..... 45°C/W
 Junction Temperature..... +150°C
 Storage Temperature Range..... -65°C to +150°C
 Lead Temperature (Soldering, 10s)..... +260°C
 ESD Susceptibility
 HBM..... 3000V
 MM..... 200V

RECOMMENDED OPERATING CONDITIONS

Input Voltage Range..... 2.5V to 5.5V
 Operating Temperature Range..... -40°C to +85°C

OVERSTRESS CAUTION

Stresses beyond those listed may cause permanent damage to the device. Functional operation of the device at these or any other conditions beyond those indicated in the operational section of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

ESD SENSITIVITY CAUTION

This integrated circuit can be damaged by ESD if you don't pay attention to ESD protection. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

DISCLAIMER

SG Micro Corp reserves the right to make any change in circuit design, specification or other related things if necessary without notice at any time.

PIN CONFIGURATION

PIN DESCRIPTION

PIN	NAME	FUNCTION
1	EN	Enable Pin. Pulling EN to ground forces the device into shutdown mode. Pulling EN to IN enables the device. EN should not be left floating and must be terminated.
2	IN	Supply Voltage Input. Must be closely decoupled to GND, with a 22 μ F or greater ceramic capacitor.
3	AIN	Analog Supply Input. Provides bias for internal circuitry.
4, 6	GND	Analog Ground.
5	FB	Feedback Pin. Receives the feedback voltage from an external resistive divider across the output. The internal voltage divider is disabled for adjustable version. (SGM6014-ADJ)
	OUT	Output Voltage Pin. An internal resistive divider divides the output voltage down for comparison to the internal reference voltage. (SGM6014-3.3)
7, 8	SW	Switching Node Pin. Connect the output inductor to this pin.
9, 10	PGND	Power Ground.
Exposed Pad	GND	Analog Ground Exposed Pad. Must be connected to GND plane.

ELECTRICAL CHARACTERISTICS

(V_{IN} = 3.6V, T_A = -40°C to +85°C, unless otherwise noted.)

PARAMETER			SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS

DETAILED DESCRIPTION

The SGM6014 is a step-down switching regulator optimized for battery-powered handheld applications. The regulator operates at typically 1.4MHz fixed switching frequency under heavy load condition to allow small external inductor and capacitors to be used for minimal printed-circuit board (PCB) area. At light load, the regulator can enter PFM mode to reduce the switching frequency, to minimize the switching loss and to maximize the battery life. The quiescent current under PFM mode with no loading is typically only 55 μ A. The supply current is typically only 0.01 μ A when the regulator is disabled.

PWM Control Scheme

The SGM6014 uses the peak-current-mode pulse-width modulation (PWM) control scheme for fast transient response and pulse-by-pulse current limiting. The current loop consists of the oscillator, the PWM comparator (COMP), current sensing circuit, and the slope compensation for the current loop stability. The current sensing circuit consists of the resistance of the P-Channel MOSFET when it is turned on and the current sense amplifier (CSA). The control reference for the current loops comes from the error amplifier (EAMP) of the voltage loop.

The PWM operation is initialized by the clock from the oscillator. The P-Channel MOSFET is turned on at the

beginning of a PWM cycle and the current in the P-Channel MOSFET starts ramping up. When the sum of the CSA output and the compensation slope reaches the control reference of the current loop, the PWM comparator COMP sends a signal to the PWM logic to turn off the P-Channel MOSFET and to turn on the N-Channel MOSFET. The N-MOSFET remains on till the end of the PWM cycle.

The output voltage is regulated by controlling the reference voltage to the current loop. The bandgap circuit outputs a 0.6V reference voltage to the voltage control loop. The feedback signal comes from the FB pin. The soft-start block only affects the operation during the start-up. The EAMP is a transconductance amplifier, which converts the voltage error signal to a current output. The voltage loop is internally compensated by an RC network.

PFM Mode

At light load the SGM6014 enters pulse frequency modulation (PFM) mode to minimize the switching loss by reducing the switching frequency.

The output voltage reduces gradually due to the load current discharging the output capacitor. When the output voltage drops to the nominal voltage, the regulator resumes normal PWM mode operation.

APPLICATION INFORMATION

Setting the Output Voltage

Figure 1 shows the basic application circuit with the SGM6014 adjustable output version. For applications requiring an adjustable output voltage, the SGM6014 adjustable version can be externally programmed. Resistors R1 and R2 in Figure 1 program the output voltage to be equal to or higher than 1.2V. To limit the bias current required for the external feedback resistor string while maintaining good noise immunity, the minimum suggested value for R2 is 41kΩ. Although a larger value will further reduce quiescent current, it will also increase the impedance of the feedback node, making it more sensitive to external noise and interference. Table 1 summarizes the resistor values for typical output voltages.

The external resistors set the output voltage according to the following equation:

$$V_{OUT} = 0.6V \times \left(1 + \frac{R1}{R2}\right) \quad R1 = \left(\frac{V_{OUT}}{0.6V} - 1\right) \times R2$$

Table 1. Standard 1% Resistors Substituted for Calculated Values

V _{OUT} (V)	R1 (kΩ)	R2 (kΩ)
1.2	150	150
1.8	300	150
3.3	450	100

When the battery input voltage decreases near the value of the output voltage, the SGM6014 allows the main switch to remain on for more than one switching cycle and increases the duty cycle until it reaches 100%. The duty cycle D of a step-down converter is defined as:

$$D = t_{ON} \cdot f_{OSC} \cdot 100\% \approx \frac{V_{OUT}}{V_{IN}} \cdot 100\%$$

where t_{ON} is the main switch on-time and f_{OSC} is the oscillator frequency. The minimum on-time is typically 100ns; therefore, the minimum duty cycle is equal to $100 \times 100\text{ns} \times f_{OSC}$ (Hz).

Inductor Selection

For most designs, the SGM6014 operates with inductor values of 1μH to 4.7μH. Small value inductors are physically smaller but require faster switching, which results in some efficiency loss. The inductor value can be derived from the following equation:

$$L = \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot \Delta I_L \cdot f_{OSC}}$$

where ΔI_L is inductor ripple current. Large value inductors lower ripple current and small value inductors result in high ripple current. Choose inductor ripple current approximately 30% of the maximum load current 2A, or $\Delta I_L = 600\text{mA}$. For output voltages above 2.0V, when light-load efficiency is important, the minimum recommended inductor is 2.2μH.

Manufacturer's specifications list both the inductor DC current rating, which is a thermal limitation, and the peak current rating, which is determined by the saturation characteristics. The inductor should not show any appreciable saturation under normal load conditions. Some inductors may meet the peak and average current ratings yet result in excessive losses due to a high DCR.

Always consider the losses associated with the DCR and its effect on the total converter efficiency when selecting an inductor. For optimum voltage-positioning load transients, choose an inductor with DC series resistance in the 20mΩ to 100mΩ range. For higher efficiency at heavy loads (above 200mA), or best load regulation (but some transient overshoot), the resistance should be kept below 100mΩ. The DC current rating of the inductor should be at least equal to the maximum load current plus half the ripple current to prevent core saturation (2A + 600mA).

Slope Compensation

The SGM6014 step-down converter uses peak current mode control with slope compensation for stability when duty cycles are greater than 50%. The slope compensation is set to maintain stability with lower value inductors which provide better overall efficiency. The output inductor value must be selected so the inductor current down slope meets the internal slope compensation requirements.

APPLICATION INFORMATION (continued)

As an example, the value of the slope compensation is set to 1.5A/μs which is large enough to guarantee stability when using a 2.2μH inductor for all output voltage levels from 1.2V to 4.4V.

The worst case external current slope (m) using the 2.2μH inductor is when $V_{OUT} = 4.4V$. To keep the output voltage stable when the duty cycle is above 50%, the internal slope compensation (m_a) should be:

$$m_a \geq \frac{1}{2}m = \frac{1}{2} \times \frac{V_{OUT}}{L} = 1A/\mu s$$

Therefore, to guarantee current loop stability, the slope of the compensation ramp must be greater than one-half of the down slope of the current waveform. So the internal slope compensated value of 1.5A/μs will guarantee stability using a 2.2μH inductor value for all output voltages from 1.2V to 4.4V.

Input Capacitor Selection

The input capacitor reduces the surge current drawn from the input and switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent high frequency switching current passing to the input. The calculated value varies with input voltage and is a maximum when V_{IN} is double the output voltage.

$$C_{IN} = \frac{\frac{V_{OUT}}{V_{IN}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right)}{\left(\frac{V_{PP}}{I_{LOAD}} - ESR\right) \cdot f_{OSC}}$$

$$C_{IN(MIN)} = \frac{1}{\left(\frac{V_{PP}}{I_{LOAD}} - ESR\right) \cdot 4 \cdot f_{OSC}}$$

A low ESR input capacitor sized for maximum RMS current must be used. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. At

least a 2.2μF input capacitor is recommended. A 22μF ceramic capacitor for most applications is sufficient. A large value may be used for improved input voltage filtering. The maximum input capacitor RMS current is:

$$I_{RMS} = I_{LOAD} \cdot \sqrt{\frac{V_{OUT}}{V_{IN}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right)}$$

The input capacitor RMS ripple current varies with the input and output voltage and will always be less than or equal to half of the total DC load current:

$$I_{RMS(MAX)} = \frac{1}{2} \cdot I_{LOAD}$$

A laboratory test set-up typically consists of two long wires running from the bench power supply to the evaluation board input voltage pins. The inductance of these wires, along with the low-ESR ceramic input capacitor, can create a high Q network that may affect converter performance. This problem often becomes apparent in the form of excessive ringing in the output voltage during load transients. Errors in the loop phase and gain measurements can also result.

Since the inductance of a short PCB trace feeding the input voltage is significantly lower than the power leads from the bench power supply, most applications do not exhibit this problem.

In applications where the input power source lead inductance cannot be reduced to a level that does not affect the converter performance, a high ESR tantalum or aluminum electrolytic capacitor should be placed in parallel with the low ESR, ESL bypass ceramic capacitor. This dampens the high Q network and stabilizes the system.

Output Capacitor Selection

The function of output capacitance is to store energy to attempt to maintain a constant voltage. The energy is stored in the capacitor's electric field due to the voltage applied.

APPLICATION INFORMATION (continued)

The value of output capacitance is generally selected to limit output voltage ripple to the level required by the specification. Since the ripple current in the output inductor is usually determined by L , V_{OUT} and V_{IN} , the series impedance of the capacitor primarily determines the output voltage ripple. The three elements of the capacitor that contribute to its impedance (and output voltage ripple) are equivalent series resistance (ESR), equivalent series inductance (ESL), and capacitance (C).

The output voltage droop due to a load transient is dominated by the capacitance of the ceramic output capacitor. During a step increase in load current, the ceramic output capacitor alone supplies the load current until the loop responds. Within three switching cycles, the loop responds and the inductor current increases to match the load current demand. The relationship of the output voltage droop during the three switching cycles to the output capacitance can be estimated by:

$$C_{OUT} = \frac{3 \cdot \Delta I_{LOAD}}{V_{DROP} \cdot f_{OSC}}$$

In many practical designs, to get the required ESR, a capacitor with much more capacitance than is needed must be selected. For both continuous and discontinuous inductor current mode operation, the ESR of the C_{OUT} needed to limit the ripple to ΔV_{OUT} , V peak-to-peak is:

$$ESR \leq \frac{\Delta V_{OUT}}{\Delta I_L}$$

Ripple current flowing through a capacitor's ESR causes power dissipation in the capacitor. This power dissipation causes a temperature increase internal to the capacitor. Excessive temperature can seriously shorten the expected life of a capacitor. Capacitors have ripple current ratings that are dependent on ambient temperature and should not be exceeded. The output capacitor ripple current is the inductor current, I_L , minus the output current. The RMS value of the ripple current flowing in the output capacitance (continuous inductor current mode operation) is given by:

$$I_{RMS} = \Delta I_L \cdot \frac{\sqrt{3}}{6} = \Delta I_L \cdot 0.289$$

ESL can be a problem by causing ringing in the low megahertz region but can be controlled by choosing low ESL capacitors, limiting lead length (PCB and capacitor), and replacing one large device with several smaller ones connected in parallel.

In conclusion, in order to meet the requirement of small output voltage ripple and regulation loop stability, ceramic capacitors with X5R or X7R dielectrics are recommended due to their low ESR and high ripple current ratings. The output ripple V_{OUT} is determined by:

$$\Delta V_{OUT} \leq \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot L \cdot f_{OSC}} \cdot \left(ESR + \frac{1}{8 \cdot f_{OSC} \cdot C_{OUT}} \right)$$

A 22 μ F ceramic capacitor can satisfy most applications.

Thermal Calculations

There are three types of losses associated with the SGM6014 step-down converter: switching losses, conduction losses, and quiescent current losses. Conduction losses are associated with the $R_{DS(ON)}$ characteristics of the power output switching devices. Switching losses are dominated by the gate charge of the power output switching devices. At full load, assuming continuous conduction mode (CCM), a simplified form of the losses is given by:

$$P_{TOTAL} = \frac{I_{LOAD}^2 \cdot [R_{DS(ON)(HS)} \cdot V_{OUT} + R_{DS(ON)(LS)} \cdot (V_{IN} - V_{OUT})]}{V_{IN}} + (t_{SW} \cdot F \cdot I_{LOAD} + I_Q) \cdot V_{IN}$$

I_Q is the step-down converter quiescent current. The t_{SW} is used to estimate the full load step-down converter switching losses.

For the condition where the step-down converter is in dropout at 100% duty cycle, the total device dissipation reduces to:

$$P_{TOTAL} = I_{LOAD}^2 \cdot R_{DS(ON)(HS)} + I_Q \cdot V_{IN}$$

Since $R_{DS(ON)}$, quiescent current, and switching losses all vary with input voltage, the total losses should be investigated over the complete input voltage range. Given the total losses, the maximum junction temperature can be derived from the θ_{JA} for the TDFN-3x3-10L package which is 45°C/W

$$T_{J(MAX)} = P_{TOTAL} \cdot \theta_{JA} + T_{AMB}$$
