**DESCRIPTION**

The A1233 is a dual-channel Hall-effect sensor IC ideal for use in speed and direction sensing applications incorporating encoder ring-magnet targets. The A1233 provides various output signals that indicate speed and direction of target rotation. The Hall elements are both photolithographically aligned to better than 1 μm. Maintaining accurate displacement between the two active Hall elements eliminates the major manufacturing hurdle encountered in fine-pitch detection applications. The A1233 is a highly sensitive, temperature-stable magnetic device ideal for use in harsh automotive and industrial environments.

The Hall elements of the A1233 are spaced 1.63 mm apart, which provides excellent speed and direction information for small-geometry targets. Extremely low-drift amplifiers guarantee symmetry between the switches to maintain signal quadrature. An on-chip regulator allows the use of this device over a wide operating voltage range of 3.5 to 24 V.

End-of-line trimming of the Hall element switchpoints provides tight matching capability. The Allegro™ high-frequency chopper stabilization technique cancels offsets in each channel, providing stable operation over the full specified temperature and voltage ranges.

**FEATURES AND BENEFITS**

- AEC-Q100 automotive qualified
- Quality Managed (QM), ISO 26262:2011 compliant
- Precisely aligned dual Hall elements
- Tightly matched magnetic switchpoints
- Speed and direction outputs
- Individual Hall element outputs (L package)
- Output short-circuit protection
- Operation from an unregulated power supply
- Wide operating temperature range
- Wide operating voltage range
- Integrated EMC-ESD protection
- Superior temperature stability and industry-leading jitter performance through use of advanced chopper stabilization topology

**PACKAGES**

- 8-pin SOIC (suffix L)
- 4-pin SIP (suffix K)

---

[Continued on the next page...](#)
DESCRIPTION (continued)

The A1233 has integrated protection against transients on the supply and output pins and short-circuit protection on all outputs.

The A1233 is available in a 4-pin SIP and a plastic 8-pin SOIC surface-mount package. Both packages are lead (Pb) free, with 100% matte-tin leadframe plating.

[1] 1 G (gauss) = 0.1 mT (militesla).

[2] When operating at maximum voltage, never exceed maximum junction temperature, $T_J(max)$. Refer to power derating curve charts.

[3] Maximum specification limit is equivalent to $I_{CC(max)} + 3$ mA.

[4] Magnetic flux density, B, is indicated as a negative value for north-polarity magnetic fields, and as a positive value for south-polarity magnetic fields. This so-called algebraic convention supports arithmetic comparison of north and south polarity values, where the relative strength of the field is indicated by the absolute value of B, and the sign indicates the polarity of the field (for example, a –100 G field and a 100 G field have equivalent strength, but opposite polarity).

The integrated circuit contains an internal voltage regulator that powers the Hall elements and both the analog and digital circuitry. This regulator allows operation over a wide supply voltage range and provides some immunity to supply noise. The device also contains logic circuitry that decodes the direction of rotation of the ring magnet.

**Quadrature/Direction Detection** Internal logic circuitry provides outputs representing the speed and direction of the magnetic field across the face of the package. For the direction signal to be appropriately updated, a quadrature relationship must be maintained between the target magnetic pole width, the pitch between the two Hall elements (E1 and E2) in the device, and, to a lesser extent, the magnetic switchpoints.

For optimal design, the device should be actuated by a ring magnet that presents to the front of the device a field with a pole width two times the Hall element-to-element spacing. This will produce a sinusoidal magnetic field whose period (denoted as $T$) is then four times the element-to-element spacing. A quadrature relationship can also be maintained for a ring magnet with fields having a period that satisfies the relationship:

$$nT/4 = 1.63\,\text{mm},$$

where $n$ is any odd integer. Therefore, ring magnets with pole-pair spacing equal to 6.52 mm ($n = 1$), 2.17 mm ($n = 3$), 1.3 mm ($n = 5$), and so forth, are permitted. The response of the device to the magnetic field produced by a rotating ring magnet is shown in figure 1. Note the phase shift between the two integrated Hall elements.

**Outputs** The device provides up to four outputs: target direction (DIR pin), E1 element output (OUTA pin), E2 element output (OUTB pin), and target speed (SPD pin).

DIR provides the direction output of the device and is defined as off (high) for targets moving in the direction from E1 to E2 and on (low) for the direction E2 to E1. SPD provides an XORed output of the two Hall elements (see figure 1). Because of internal delays, DIR is always updated before SPD and is updated at every transition of OUTA and OUTB (internal) allowing the use of up-down counters without the loss of pulses.

**Power-on State** At power on, the logic circuitry is reset to provide an off (high) state for all the outputs. If any of the channels is subjected to a field greater than $B_{\text{OP}}$, the internal logic will set accordingly, and the outputs will switch to the expected state.

**Power-on Time** This characteristic, $t_{\text{ON}}$, is the elapsed time from when the supply voltage reaches the device supply minimum until the device output becomes valid (see figure 2).
**APPLICATION INFORMATION**

**Functional Safety.** The A1233 complies with the international standard for automotive functional safety, ISO 26262:2011, as a Quality Managed (QM) product. The device is classified as a SEooC (Safety Element out of Context) and can be easily integrated into safety-critical systems requiring higher ASIL ratings that incorporate external diagnostics or use measures such as redundancy. Safety documentation will be provided to support and guide the integration process. For further information, contact your local Allegro field applications engineer or sales representative.

**Operation with Fine-Pitch Ring Magnets.** For targets with a circular pitch of less than 4 mm, a performance improvement can be observed by rotating the front face of the device (see below). This rotation decreases the effective Hall element-to-element spacing, provided that the Hall elements are not rotated beyond the width of the target.

**Applications.** It is strongly recommended that an external 0.1 µF bypass capacitor be connected (in close proximity to the device) between the supply and ground of the device to reduce both external noise and noise generated by the internal logic.

The simplest form of magnet that will operate these devices is a ring magnet. Other methods of operation, such as linear magnets, are possible. Extensive applications information on magnets and Hall-effect sensor ICs is also available in the “Hall-Effect IC Applications Guide” which can be found on the Allegro website, www.allegromicro.com.

---

**Typical Application**

(Using regulated supply; K package configuration shown)

- Resistor is optional, depending on Conducted Immunity requirements
POWER DERATING

The device must be operated below the maximum junction temperature of the device, $T_{J\text{ (max)}}$. Under certain combinations of peak conditions, reliable operation may require derating supplied power or improving the heat dissipation properties of the application. This section presents a procedure for correlating factors affecting operating $T_J$. (Thermal data is also available on the Allegro MicroSystems website.)

The Package Thermal Resistance, $R_{\theta JA}$, is a figure of merit summarizing the ability of the application and the device to dissipate heat from the junction (die), through all paths to the ambient air. Its primary component is the Effective Thermal Conductivity, $K$, of the printed circuit board, including adjacent devices and traces. Radiation from the die through the device case, $R_{\theta JC}$, is a relatively small component of $R_{\theta JA}$. Ambient air temperature, $T_A$, and air motion are significant external factors, damped by overmolding.

The effect of varying power levels (Power Dissipation, $P_D$), can be estimated. The following formulas represent the fundamental relationships used to estimate $T_J$, at $P_D$:

\[
P_D = V_{IN} \times I_{IN} \quad (1)
\]

\[
\Delta T = P_D \times R_{\theta JA} \quad (2)
\]

\[
T_J = T_A + \Delta T \quad (3)
\]

For example, given common conditions such as: $T_A = 25^\circ C$, $V_{CC} = 12 V$, $I_{CC} = 4.5 mA$, and $R_{\theta JA} = 177^\circ C/W$, then:

\[
P_D = V_{CC} \times I_{CC} = 12 V \times 4.5 mA = 54 mW
\]

\[
\Delta T = P_D \times R_{\theta JA} = 54 mW \times 177^\circ C/W = 9.6^\circ C
\]

\[
T_J = T_A + \Delta T = 25^\circ C + 9.6^\circ C = 34.6^\circ C
\]

A worst-case estimate, $P_{D\text{ (max)}}$, represents the maximum allowable power level, without exceeding $T_{J\text{ (max)}}$, at a selected $R_{\theta JA}$ and $T_A$.

Example: Reliability for $V_{CC}$ at $T_A = 150^\circ C$.

Observe the worst-case ratings for the device, specifically: $R_{\theta JA} = 177^\circ C/W$, $T_{J\text{ (max)}} = 165^\circ C$, $V_{CC\text{ (max)}} = 24 V$, and $I_{CC\text{ (max)}} = 8 mA$.

Calculate the maximum allowable power level, $P_{D\text{ (max)}}$. First, invert equation 3:

\[
\Delta T_{\text{ (max)}} = T_{J\text{ (max)}} - T_A = 165^\circ C - 150^\circ C = 15^\circ C
\]

This provides the allowable increase to $T_J$ resulting from internal power dissipation.

Then, invert equation 2:

\[
P_{D\text{ (max)}} = \frac{\Delta T_{\text{ (max)}}}{R_{\theta JA}} = \frac{15^\circ C}{177^\circ C/W} = 84.7 mW
\]

Finally, invert equation 1 with respect to voltage:

\[
V_{CC\text{ (est)}} = \frac{P_{D\text{ (max)}}}{I_{CC\text{ (max)}}} = \frac{84.7 mW}{8 mA} = 10.59 V
\]

The result indicates that, at $T_A$, the application and device can dissipate adequate amounts of heat at voltages $\leq V_{CC\text{ (est)}}$.

Compare $V_{CC\text{ (est)}}$ to $V_{CC\text{ (max)}}$. If $V_{CC\text{ (est)}} \leq V_{CC\text{ (max)}}$, then reliable operation between $V_{CC\text{ (est)}}$ and $V_{CC\text{ (max)}}$ requires enhanced $R_{\theta JA}$. If $V_{CC\text{ (est)}} \geq V_{CC\text{ (max)}}$, then operation between $V_{CC\text{ (est)}}$ and $V_{CC\text{ (max)}}$ is reliable under these conditions.
Package L, 8-Pin SOIC

For Reference Only; not for tooling use (reference MS-012AA)
Dimensions in millimeters
Dimensions exclusive of mold flash, gate burn, and dambar protrusions
Exact case and lead configuration at supplier discretion within limits shown
Terminal #1 mark area
Branding scale and appearance at supplier discretion
Reference land pattern layout (reference IPC7351 SOIC127P600X175-8M); all pads a minimum of 0.20 mm from all adjacent pads; adjust as necessary to meet application process requirements and PCB layout tolerances
Active Area Depth 0.40 NOM
Hall elements (E1 and E2); not to scale
