

Please note that Cypress is an Infineon Technologies Company.

The document following this cover page is marked as “Cypress” document as this is the company that originally developed the product. Please note that Infineon will continue to offer the product to new and existing customers as part of the Infineon product portfolio.

Continuity of document content

The fact that Infineon offers the following product as part of the Infineon product portfolio does not lead to any changes to this document. Future revisions will occur when appropriate, and any changes will be set out on the document history page.

Continuity of ordering part numbers

Infineon continues to support existing part numbers. Please continue to use the ordering part numbers listed in the datasheet for ordering.

General Description

PSoC® 6 MCU is a high-performance, ultra-low-power and secured MCU platform, purpose-built for IoT applications. The PSoC 64 product line, based on the PSoC 6 MCU platform, features out-of-box security functionality, providing an isolated root-of-trust with true attestation and provisioning services. In addition, it delivers a pre-configured secured execution environment which supports system software for various IoT platforms; and enables TLS authentication, secured storage, and secured firmware management. PSoC 64 also includes a rich execution environment for application development, with RTOS support that communicates with the secured execution environment.

Features

32-bit Dual CPU Subsystem

Note: In PSoC 64 the Cortex M0+ is reserved for system functions, and is not available for applications.

- 150-MHz Arm® Cortex®-M4F (CM4) CPU with single-cycle multiply, floating point, and memory protection unit (MPU)
- 100-MHz Cortex-M0+ (CM0+) CPU with single-cycle multiply and MPU
- User-selectable core logic operation at either 1.1 V or 0.9 V
- Active CPU current slope with 1.1-V core operation
 - Cortex-M4: 40 µA/MHz
 - Cortex-M0+: 20 µA/MHz
- Active CPU current slope with 0.9-V core operation
 - Cortex-M4: 22 µA/MHz
 - Cortex-M0+: 15 µA/MHz
- Three DMA controllers

Memory Subsystem

- 384-KB application flash, 32-KB auxiliary flash (AUXflash), and 32-KB supervisory flash (SFlash); read-while-write (RWW) support. Two 8-KB flash caches, one for each CPU.
- 176-KB SRAM with programmable power control and retention granularity
- One-time-programmable (OTP) 1-Kb eFuse array

Hardware-Based Root-of-Trust (RoT)

- RoT based on immutable boot-up code, flash content hash, and Cypress public key that ensures firmware integrity prior to provisioning
- Supports trusted RoT handover to maintain chain of trust and establish OEM trust anchor for secured boot
- Device generates a unique device ID and a device secret key during the provisioning process, which can be used for attestation and signing

Immutable "Secure Boot" Support

- Flexible chain of trust can use different signatures for different images
- ECC-based image signature validation

Cypress Bootloader

- Open source MCUBoot^[1] based bootloader optimized for PSoC 64
- Pre-built bootloader binary capable of validating, launching and updating signed user application images
- Tightly integrated with provisioned debug and boot policies to inherit and implement security policies

Low-Power 1.7-V to 3.6-V Operation

- Six power modes for fine-grained power management
- On-chip DC-DC buck converter, <1 µA quiescent current
- Backup domain with 64 bytes of memory and real-time clock

Flexible Clocking Options

- 8-MHz internal main oscillator (IMO) with ±2% accuracy
- Ultra-low-power 32-kHz internal low-speed oscillator (ILO)
- On-chip crystal oscillators (16 to 35 MHz, and 32 kHz)
- Phase-locked loop (PLL) for multiplying clock frequencies
- Frequency-locked loop (FLL) for multiplying IMO frequency
- Integer and fractional peripheral clock dividers

Quad-SPI (QSPI)/Serial Memory Interface (SMIF)

- Execute-In-Place (XIP) from external quad SPI flash
- On-the-fly encryption and decryption
- 4-KB cache for greater XIP performance with lower power
- Supports single, dual, and quad interfaces with throughput up to 320 Mbps

Segment LCD Drive

- Supports up to 52 segments and up to 8 commons.
- Operates in system Deep Sleep mode

Serial Communication

- Seven run-time configurable serial communication blocks (SCBs)
 - Six SCBs: configurable as SPI, I²C, or UART
 - One Deep Sleep SCB: configurable as SPI or I²C
- USB Full-Speed device interface
- One SD Host Controller/eMMC/SD controller
- One CAN FD block

Note

1. For details, refer to <https://mcuboot.com/>.

Timing and Pulse-Width Modulation

- Twelve timer/counter/pulse-width modulators (TCPWMs)
- Center-aligned, edge, and pseudo-random modes
- Comparator-based triggering of kill signals

Programmable Analog

- 12-bit 2-Msps SAR ADC with differential and single-ended modes and 16-channel sequencer with result averaging
- Two low-power comparators available in system Deep Sleep and Hibernate modes
- Built-in temperature sensor connected to ADC

Up to 53 Programmable GPIOs

- Two Smart I/O™ ports (8 I/Os) enable Boolean operations on GPIO pins; available during system Deep Sleep
- Programmable drive modes, strengths, and slew rates
- Two overvoltage-tolerant (OVT) pins

Capacitive Sensing

- Cypress CapSense® sigma-delta (CSD) provides best-in-class signal-to-noise ratio (SNR), liquid tolerance, and proximity sensing
- Enables dynamic usage of both self and mutual sensing
- Automatic hardware tuning (SmartSense™)

Cryptography Accelerator

- Hardware acceleration for symmetric and asymmetric cryptographic methods and hash functions
- True random number generation (TRNG) function

Packages

- 68 QFN

Device Identification and Revisions

- Product line ID (12-bit): 0x105
- Major/Minor die revision ID: 1/2
- Firmware revisions: ROM Boot: 7.1, Flash Boot: 4.0.2.1842 (see [Boot Code](#) section)

This product line has a JTAG ID which is available through the SWJ interface. It is a 32-bit ID, where:

- The most significant digit is the device revision, based on the Major Die Revision
- The next four digits correspond to the part number, for example "E4B0" as a hexadecimal number
- The three least significant digits are the manufacturer ID, in this case "069" as a hexadecimal number

The Silicon ID system call can be used by firmware to get Silicon ID and ROM Boot data. For more information, see the [technical reference manual \(TRM\)](#).

The Flash Boot version can be read directly from designated addresses 0x1600 2004 and 0x1600 2018. For more information, see the [technical reference manual \(TRM\)](#).

PSoC 6 MCU Resources

Cypress provides a wealth of data at www.cypress.com to help you select the right PSoC device and quickly and effectively integrate it into your design. The following is an abbreviated list of resources for PSoC 6 MCU:

- **Overview:** [PSoC Portfolio](#), [PSoC Roadmap](#)
- **Product Selectors:** [PSoC 6 MCU](#)
- **Application Notes** cover a broad range of topics, from basic to advanced level, and include the following:
 - [AN221774](#): Getting Started with PSoC 6 MCU
 - [AN218241](#): PSoC 6 MCU Hardware Design Guide
 - [AN213924](#): PSoC 6 MCU Device Firmware Update Guide
 - [AN215656](#): PSoC 6 MCU Dual-CPU System Design
 - [AN219528](#): PSoC 6 MCU Power Reduction Techniques
 - [AN85951](#): PSoC 4, PSoC 6 MCU CapSense Design Guide
- **Code Examples** demonstrate product features and usage, and are also available on [Cypress GitHub repositories](#).
- **Technical Reference Manuals (TRMs)** provide detailed descriptions of PSoC 6 MCU architecture and registers.
- **PSoC 6 MCU Programming Specification** provides the information necessary to program PSoC 6 MCU nonvolatile memory
- **Development Tools**
 - **ModusToolbox®** software enables cross platform code development with a robust suite of tools and software libraries
 - “Secure Boot” SDK includes all required libraries, tools, and sample code to provision and develop applications for PSoC 64 MCUs.
 - **CY8CPROTO-064B0S3** PSoC 64 “Secure Boot” Prototyping Kit: a low-cost hardware platform that enables design and debug of the PSoC 64 CYB06445LQI-S3D42 product line.
 - **PSoC 6 CAD libraries** provide footprint and schematic support for common tools. [BSDL files](#) and [IBIS models](#) are also available.
- **Training Videos** are available on a wide range of topics including the [PSoC 6 MCU 101 series](#)
- **Cypress Developer Community** enables connection with fellow PSoC developers around the world, 24 hours a day, 7 days a week, and hosts a dedicated [PSoC 6 MCU Community](#)

ModusToolbox™ IDE and the PSoC 6 SDK

ModusToolbox Software is Cypress' comprehensive collection of multi-platform tools and software libraries that enable an immersive development experience for creating converged MCU and wireless systems. It is:

- Comprehensive - it has the resources you need
- Flexible - you can use the resources in your own workflow
- Atomic - you can get just the resources you want

Cypress provides a large collection of code [repositories on GitHub](#). This includes:

- Board Support Packages (BSPs) aligned with Cypress kits
- Low-level resources, including a hardware abstraction layer (HAL) and peripheral driver library (PDL)
- Middleware enabling industry-leading features such as CapSense, Bluetooth Low Energy, and mesh networks
- An extensive set of thoroughly tested [code example applications](#)

Note: The HAL provides a high-level, simplified interface to configure and use the hardware blocks on Cypress MCUs. It is a generic interface that can be used across multiple product families. For example, it wraps the PSoC 6 PDL with a simplified API, but the PDL exposes all low-level peripheral functionality. You can leverage the HAL's simpler and more generic interface for most of an application, even if one portion requires finer-grained control.

ModusToolbox Software is IDE-neutral and easily adaptable to your workflow and preferred development environment. It includes a project creator, peripheral and library configurators, a library manager, as well as the optional Eclipse IDE for ModusToolbox. For information on using Cypress tools, refer to the documentation delivered with ModusToolbox software, and [AN228571: Getting Started with PSoC 6 MCU on ModusToolbox](#).

Figure 1. ModusToolbox Software Tools

Blocks and Functionality

Figure 2 shows the major subsystems and a simplified view of their interconnections. The color coding shows the lowest power mode where the particular block is still functional (for example, the SRAM is functional down to system Deep Sleep mode).

Figure 2. Block Diagram

This product line has up to 512 KB of flash; however 128 KB is reserved for system usage, leaving 384 KB for applications. The 32-KB auxiliary flash (AUXflash) is also reserved, and is not available for applications. It also has up to 256 KB of SRAM; however 80 KB is reserved for system usage, leaving 176 KB for applications.

The PSoC 64 devices offer an immutable, RoT-based boot-up process, which allows only signed applications to be booted up. In addition, user assets such as keys and debug policies can be provisioned on the device in an HSM environment and made immutable. PSoC 64 also allows for root-of-trust based cryptography services which can be accessed using system calls.

There are three debug access ports, one each for CM4 and CM0+, and a system port. All debug and test interfaces can be permanently disabled during final production provisioning to avoid any malicious reprogramming or reading of flash and register contents.

PSoC 6 MCU devices include extensive support for programming, testing, debugging, and tracing both hardware and firmware. All device interfaces can be permanently disabled for applications concerned about a reprogrammed device or starting and interrupting flash programming sequences. All programming, debug, and test interfaces can be disabled.

Complete debug-on-chip functionality enables full device debugging in the final system using the standard production device. It does not require special interfaces, debugging pods, simulators, or emulators. Only the standard programming connections are required to fully support debug.

The Eclipse IDE for ModusToolbox provides fully integrated programming and debug support for these devices. The SWJ (SWD and JTAG) interface is fully compatible with industry-standard third party probes. With the ability to disable debug features, with very robust flash protection, and by allowing customer-proprietary functionality to be implemented in on-chip programmable blocks, PSoC 6 provides multiple levels of device security.

Functional Description

The following sections provide an overview of the features, capabilities and operation of each functional block identified in the block diagram in [Figure 2](#). For more detailed information, refer to the following documentation:

■ Board Support Package (BSP) Documentation

BSPs are available on [GitHub](#). They are aligned with Cypress kits and provide files for basic device functionality such as hardware configuration files, startup code, and linker files. The BSP also includes other libraries that are required to support a kit. Each BSP has its own documentation, but typically includes an API reference such as the example [here](#). This [search link](#) finds all currently available BSPs on the Cypress GitHub site.

■ Hardware Abstraction Layer API Reference Manual

The Cypress Hardware Abstraction Layer (HAL) provides a high-level interface to configure and use hardware blocks on Cypress MCUs. It is a generic interface that can be used across multiple product families. You can leverage the HAL's simpler and more generic interface for most of an application, even if one portion requires finer-grained control. The [HAL API Reference](#) provides complete details. Example applications that use the HAL download it automatically from the GitHub repository.

■ Peripheral Driver Library (PDL) Application Programming Interface (API) Reference Manual

The Peripheral Driver Library (PDL) integrates device header files and peripheral drivers into a single package and supports all PSoC 6 MCU product lines. The drivers abstract the hardware functions into a set of easy-to-use APIs. These are fully documented in the [PDL API Reference](#). Example applications that use the PSoC 6 PDL download it automatically from the GitHub repository.

■ Architecture Technical Reference Manual (TRM)

The architecture TRM provides a detailed description of each resource in the device. This is the next reference to use if it is necessary to understand the operation of the hardware below the software provided by PDL. It describes the architecture and functionality of each resource and explains the operation of each resource in all modes. It provides specific guidance regarding the use of associated registers.

■ Register Technical Reference Manual

The register TRM provides a complete list of all registers in the device. It includes the breakdown of all register fields, their possible settings, read/write accessibility, and default states. All registers that have a reasonable use in typical applications have functions to access them from within PDL. Note that ModusToolbox and PDL may provide software default conditions for some registers that are different from and override the hardware defaults.

CPU and Memory Subsystem

PSoC 6 has multiple bus masters, as [Figure 2](#) shows. They are: CPUs, DMA controllers, QSPI, USB, SD Host controller, and a Crypto block. Generally, all memory and peripherals can be accessed and shared by all bus masters through multi-layer Arm AMBA high-performance bus (AHB) arbitration. Accesses between CPUs can be synchronized using an inter-processor communication (IPC) block.

CPUs

There are two Arm Cortex CPUs:

The Cortex-M4 (CM4) has single-cycle multiply, a floating-point unit (FPU), and a memory protection unit (MPU). It can run at up to 150 MHz. This is the main CPU, designed for a short interrupt response time, high code density, and high throughput.

CM4 implements a version of the Thumb instruction set based on Thumb-2 technology (defined in the [Armv7-M Architecture Reference Manual](#)).

The Cortex-M0+ (CM0+) has single-cycle multiply, and an MPU. It can run at up to 100 MHz; however, for CM4 speeds above 100 MHz, CM0+ and bus peripherals are limited to half the speed of CM4. Thus, for CM4 running at 150 MHz, CM0+ and peripherals are limited to 75 MHz.

In PSoC 64, the initial CM0+ frequency is set according to a provisioned security policy (see PSoC 64 Security). The frequency ranges from 8 MHz to 50 MHz. For more information, see the [Register TRM and Architecture TRM](#).

CM0+ is the secondary CPU; it is used to implement system calls and device-level security, safety, and protection features. CM0+ provides a secured, uninterruptible boot function. This helps ensure that post boot, system integrity is checked and memory and peripheral access privileges are enforced.

CM0+ implements the Armv6-M Thumb instruction set (defined in the [Armv6-M Architecture Reference Manual](#)).

The CPUs have the following power draw, at $V_{DD} = 3.3$ V and using the internal buck regulator:

Table 1. Active Current Slope at $V_{DD} = 3.3$ V Using the Internal Buck Regulator

		System Power Mode	
		ULP	LP
CPU	Cortex-M0+	15 μ A/MHz	20 μ A/MHz
	Cortex-M4	22 μ A/MHz	40 μ A/MHz

The CPUs can be selectively placed in their Sleep and Deep Sleep power modes as defined by Arm.

Both CPUs have nested vectored interrupt controllers (NVIC) for rapid and deterministic interrupt response, and wakeup interrupt controllers (WIC) for CPU wakeup from Deep Sleep power mode.

The CPUs have extensive debug support. PSoC 6 has a debug access port (DAP) that acts as the interface for device programming and debug. An external programmer or debugger (the "host") communicates with the DAP through the device serial wire debug (SWD) or Joint Test Action Group (JTAG) interface pins. Through the DAP (and subject to device security

restrictions), the host can access the device memory and peripherals as well as the registers in both CPUs.

Each CPU offers debug and trace features as follows:

- CM4 supports six hardware breakpoints and four watchpoints, 4-bit embedded trace macrocell (ETM), serial wire viewer (SWV), and printf()-style debugging through the single wire output (SWO) pin.
- CM0+ supports four hardware breakpoints and two watchpoints, and a micro trace buffer (MTB) with 4-KB dedicated RAM.

PSoC 6 also has an Embedded Cross Trigger for synchronized debugging and tracing of both CPUs.

Interrupts

This product line has 174 system and peripheral interrupt sources, and supports interrupts and system exceptions on both CPUs. CM4 has 174 interrupt request lines (IRQ), with the interrupt source 'n' directly connected to IRQn. CM0+ has eight interrupts IRQ[7:0] with configurable mapping of one or more interrupt sources to any of the IRQ[7:0]. CM0+ also supports eight internal (software only) interrupts.

Each interrupt supports configurable priority levels (eight levels for CM4 and four levels for CM0+). Up to four system interrupts can be mapped to each of the CPUs' non-maskable interrupts (NMI). Up to 39 interrupt sources are capable of waking the device from Deep Sleep power mode using the WIC. Refer to the [technical reference manual \(TRM\)](#).

InterProcessor Communication (IPC)

In addition to the Arm SEV and WFE instructions, a hardware InterProcessor Communication (IPC) block is included. It includes 16 IPC channels and 16 IPC interrupt structures. The IPC channels can be used to implement data communication between the processors. Each IPC channel also implements a locking scheme which can be used to manage shared resources. The IPC interrupts let one processor interrupt the other, signaling an event. This is used to trigger events such as notify and release of the corresponding IPC channels. Some IPC channels and other resources are reserved, as [Table 2](#) shows:

Table 2. Distribution of IPC Channels and Other Resources

Resources Available	Resources Consumed
IPC channels, 16 available	13 reserved
IPC interrupts, 16 available	13 reserved
Other interrupts	1 reserved
CM0+ NMI	Reserved
Other resources: clock dividers, DMA channels, etc.	4 CM0+ interrupt mux

Direct Memory Access (DMA) Controllers

This product line has three DMA controllers, with 32, 29, and 2 channels, which support CPU-independent accesses to memory and peripherals. The descriptors for DMA channels can be in SRAM or flash. Therefore, the number of descriptors is limited only by the size of the memory. Each descriptor can transfer data in two nested loops with configurable address increments to the source and destination. The size of data transfer per descriptor varies based on the type of DMA channel. Refer to the [technical reference manual \(TRM\)](#) for detail.

Cryptography Accelerator (Crypto)

This subsystem consists of hardware implementation and acceleration of cryptographic functions and random number generators.

The Crypto subsystem supports the following:

- Encryption/Decryption Functions
 - Data Encryption Standard (DES)
 - Triple DES (3DES)
 - Advanced Encryption Standard (AES) (128-, 192-, 256-bit)
 - Elliptic Curve Cryptography (ECC)
 - RSA cryptography functions
- Hashing functions
 - Secure Hash Algorithm (SHA)
 - SHA-1
 - SHA-224/-256/-384/-512
- Message authentication functions (MAC)
 - Hashed message authentication code (HMAC)
 - Cipher-based message authentication code (CMAC)
- 32-bit cyclic redundancy code (CRC) generator
- Random number generators
 - Pseudo random number generator (PRNG)
 - True random number generator (TRNG)

Protection Units

This product line has multiple types of protection units to control erroneous or unauthorized access to memory and peripheral registers. CM4 and CM0+ have Arm MPUs for protection at the bus master level. Other bus masters use additional MPUs. Shared memory protection units (SMPUs) help implement protection for memory resources that are shared among multiple bus masters. Peripheral protection units (PPU) are similar to SMPUs but are designed for protecting the peripheral register space.

Protection units support memory and peripheral access attributes including address range, read/write, code/data, privilege level, secured/non-secured, and protection context. Some protection unit resources are reserved for system usage; see the [technical reference manual](#) for details. Up to eight protection contexts (boot is in protection context 0) allow access privileges for memory and system resources to be set by the boot process per protection context by bus master and code privilege level.

In PSoC 64, multiple protection contexts are used to isolate the different security levels within the device. The CM0+ makes use of several of them during the boot sequence, bootloading, system calls, etc. Protection context 6 is used for the user application code that runs on the CM4 CPU. The SMPUs are set up by default and cannot be modified by the user. See section 8 in the Architecture TRM for the protection context assignment. See section 8 in the Architecture TRM for the protection context assignment.

Memory

PSoC 6 contains flash, SRAM, ROM, and eFuse memory blocks.

■ Flash

There is up to 512 KB of flash; however 128 KB is reserved for system usage, leaving 384 KB for applications. The 32-KB auxiliary flash (AUXflash) is also reserved, and is not available for applications.

There are also two 32-KB flash sectors:

- AUXflash
- Supervisory flash (SFlash). Data stored in Sflash includes device trim values, [Flash Boot](#) code, and encryption keys. After the device transitions into the “Secure” lifecycle stage, SFlash can no longer be changed.

The flash uses 128-bit-wide accesses to reduce power. Write operations can be performed at the row level. A row is 512 bytes. Read operations are supported in both Low Power and Ultra-Low Power modes, however write operations may not be performed in Ultra-Low Power mode.

The flash controller has two caches, one for each CPU. Each cache is 8 KB, with 4-way set associativity.

■ SRAM

Up to 256 KB of SRAM is provided, however, 80 KB is reserved for system usage, leaving 176 KB for applications.. Power control and retention granularity is implemented in 32-KB blocks allowing the user to control the amount of memory retained in Deep Sleep. Memory is not retained in Hibernation mode.

■ ROM

The 64-KB ROM, also referred to as the supervisory ROM (SROM), provides code ([ROM Boot](#)) for several system functions. The ROM contains device initialization, flash write, security, eFuse programming, and other system-level routines. ROM code is executed only by the CM0+ CPU, in protection context 0. A system function can be initiated by either CPU, or through the DAP. This causes an NMI in CM0+, which causes CM0+ to execute the system function.

■ eFuse

A one-time-programmable (OTP) eFuse array consists of 1024 bits, all of which are reserved for system use. The bits are used for storing hash values, unique IDs, or other similar PSoC 64 parameters.

Each fuse is individually programmed; once programmed (or “blown”), its state cannot be changed. Blowing a fuse transitions it from the default state of 0 to 1. To program an eFuse, V_{DDIO0} must be at $2.5\text{ V} \pm 5\%$, at 14 mA.

Because blowing an eFuse is an irreversible process, programming is recommended only in mass production under controlled factory conditions. For more information, see [PSoC 6 MCU Programming Specifications](#).

Boot Code

Two blocks of code, [ROM Boot](#) and [Flash Boot](#), are pre-programmed into the device and work together to provide device startup and configuration, basic security features, life-cycle stage management and other system functions.

■ ROM Boot

On a device reset, the boot code in ROM is the first code to execute. This code performs the following:

- Integrity checks of flash boot code
 - Device trim setting (calibration)
 - Setting the device protection units
 - Setting device access restrictions for “Secure” lifecycle states
- ROM cannot be changed and acts as the root of trust in a secured system.

■ Flash Boot

Flash boot is firmware stored in SFlash that ensures that only a validated application may run on the device. It also ensures that the firmware image has not been modified, such as by a malicious third party.

Flash boot:

- Is validated by ROM Boot
- Runs after ROM Boot and before the user application
- Enables system calls
- Enables provisioning and device policy features
- Implements RoT-based services for cryptography
- Provides secured storage for keys and certificates
- Validates and launches first image based on policies provisioned in the device
- Uses mbed TLS v2.24

If the user application cannot be validated, then flash boot ensures that the device is transitioned into a safe state. Refer to the [PSoC 64 Security](#) section for more details.

Memory Map

Both CPUs have a fixed address map, with shared access to memory and peripherals. The 32-bit (4 GB) address space is divided into the Arm-defined regions shown in [Table 8](#). Note that code can be executed from the Code and External RAM regions.

Table 3. Address Map for CM4 and CM0+

Address Range	Name	Use
0x0000 0000 – 0x1FFF FFFF	Code	Program code region. Data can also be placed here. It includes the exception vector table, which starts at address 0.
0x2000 0000 – 0x3FFF FFFF	SRAM	Data region. This region is not supported in PSoC 6.
0x4000 0000 – 0x5FFF FFFF	Peripheral	All peripheral registers. Code cannot be executed from this region. CM4 bit-band in this region is not supported in PSoC 6.
0x6000 0000 – 0x9FFF FFFF	External RAM	SMIF or Quad SPI, (see the Quad-SPI (QSPI)/Serial Memory Interface (SMIF) section). Code can be executed from this region.
0xA000 0000 – 0xDFFF FFFF	External Device	Not used.
0xE000 0000 – 0xE00F FFFF	Private Peripheral Bus	Provides access to peripheral registers within the CPU core.
0xE010 0A000 – 0xFFFF FFFF	Device	Device-specific system registers.

The device memory map shown in [Table 4](#) applies to both CPUs. That is, the CPUs share access to all PSoC 6 MCU memory and peripheral registers.

Table 4. Internal Memory Address Map for CM4 and CM0+

Address Range	Memory Type	Size
0x0000 0000 – 0x0000 FFFF	ROM	64 KB
0x0800 0000 – 0x0802 BFFF 0x0802 C000 – 0x0803 FFFF	Application SRAM System SRAM	Up to 176 KB 80 KB
0x1000 0000 – 0x1005 FFFF 0x1006 0000 – 0x1007 FFFF	Application flash Secured code flash Used for secured boot, secured bootloader, and system calls	Up to 384 KB 128 KB
0x1400 0000 – 0x1400 7FFF	Auxiliary flash, reserved for system use	32 KB
0x1600 0000 – 0x1600 7FFF	Supervisory flash, for secured access	32 KB

Note that PSoC 6 SRAM is located in the Arm Code region for both CPUs (see [Table 8](#)). There is no physical memory located in the CPUs' Arm SRAM regions.

System Resources

Power System

The power system provides assurance that voltage levels are as required for each respective mode and will either delay mode entry (on power-on reset (POR), for example) until voltage levels are as required for proper function or generate resets (brown-out detect (BOD)) when the power supply drops below specified levels. The design guarantees safe chip operation between power supply voltage dropping below specified levels (for example, below 1.7 V) and the reset occurring. There are no voltage sequencing requirements.

The V_{DD} supply (1.7 to 3.6 V) powers an on-chip buck regulator or a low-dropout regulator (LDO), selectable by the user. In addition, both the buck and the LDO offer a selectable (0.9 or 1.1 V) core operating voltage (V_{CCD}). The selection lets users choose between two system power modes:

- System Low Power (LP) operates V_{CCD} at 1.1 V and offers high performance, with no restrictions on device configuration.
- System Ultra Low Power (ULP) operates V_{CCD} at 0.9 V for exceptional low power, but imposes limitations on clock speeds.

In addition, a backup domain adds an “always on” functionality using a separate power domain supplied by a backup supply (V_{BACKUP}) such as a battery or supercapacitor.

It includes a real-time clock (RTC) with alarm feature, supported by a 32.768-kHz watch crystal oscillator (WCO), and power-management IC (PMIC) control. Refer to [Power Supply Considerations](#) for more details.

Power Modes

PSoC 6 MCU can operate in four system and three CPU power modes. These modes are intended to minimize the average power consumption in an application. For more details on power modes and other power-saving configuration options, see the application note, [AN219528: PSoC 6 MCU Low-Power Modes and Power Reduction Techniques](#) and the [Architecture TRM, Power Modes chapter](#) (contact your local Cypress sales representative for the latest TRM).

Power modes supported by PSoC 6 MCUs, in order of decreasing power consumption, are:

- System Low Power (LP) – All peripherals and CPU power modes are available at maximum speed
- System Ultra Low Power (ULP) – All peripherals and CPU power modes are available, but with limited speed
- CPU Active – CPU is executing code in system LP or ULP mode

- CPU Sleep – CPU code execution is halted in system LP or ULP mode
- CPU Deep Sleep – CPU code execution is halted and system Deep Sleep is requested in system LP or ULP mode
- System Deep Sleep – Only low-frequency peripherals are available after both CPUs enter CPU Deep Sleep mode
- System Hibernate – Device and I/O states are frozen and the device resets on wakeup

CPU Active, Sleep, and Deep Sleep are standard Arm-defined power modes supported by the Arm CPU instruction set architecture (ISA). System LP, ULP, Deep Sleep and Hibernate modes are additional low-power modes supported by PSoC 6 MCU.

Clock System

[Figure 15](#) shows that the clock system of this product line consists of the following:

- Internal main oscillator (IMO)
- Internal low-speed oscillator (ILO)
- Watch crystal oscillator (WCO)
- External MHz crystal oscillator (ECO)
- External clock input
- One phase locked-loop (PLL)
- One frequency-locked loop (FLL)

Clocks may be buffered and brought out to a pin on a Smart I/O port.

The default clocking when the application starts is CLK_HF[0] being driven by the IMO and the FLL. CLK_HF[0], clk_fast, clk_peri, and clk_slow are all either 50 MHz (LP mode) or 25 MHz (ULP mode). All other clocks, including all peripheral clocks, are off.

Internal Main Oscillator (IMO)

The IMO is the primary source of internal clocking. It is trimmed at the factory to achieve the specified accuracy. The IMO frequency is 8 MHz and tolerance is $\pm 2\%$.

The IMO can operate in system Deep Sleep mode to drive the LCD block for better contrast (and higher power) than is possible with the 32-kHz mode.

Internal Low-Speed Oscillator (ILO)

The ILO is a very low power oscillator, nominally 32 kHz, which operates in all power modes. The ILO can be calibrated against a higher accuracy clock for better accuracy.

Figure 3. Clocking Diagram

External Crystal Oscillators

Figure 4 shows all of the external crystal oscillator circuits for this product line. The component values shown are typical; check the [ECO Specifications](#) for the crystal values, and the crystal datasheet for the load capacitor values. The ECO and WCO require balanced external load capacitors. For more information, see the TRM and [AN218241, PSoC 6 MCU Hardware Design Considerations](#).

Figure 4. Oscillator Circuits

If the ECO is used, note that its performance is affected by GPIO switching noise. GPIO ports should be used as [Table 5](#) shows. See also [Table 6](#) for additional restrictions for general analog subsystem use.

Table 5. ECO Usage Guidelines

Ports	Max Frequency	Drive Strength for $V_{DD} \leq 2.7$ V	Drive Strength for $V_{DD} \leq 2.7$ V
Port 11	60 MHz for SMIF (QSPI)	DRIVE_SEL 2	DRIVE_SEL 3
Ports 12 and 13	Slow slew rate setting	No restrictions	No restrictions

Watchdog Timers (WDT, MCWDT)

PSoC 6 MCU has one WDT and two multi-counter WDTs (MCWDT). The WDT has a 16-bit free-running counter. Each MCWDT has two 16-bit counters and one 32-bit counter, with multiple operating modes. All of the 16-bit counters can generate a watchdog device reset. All of the counters can generate an interrupt on a match event.

The WDT is clocked by the ILO. It can generate interrupt/wakeup in system LP/ULP, Deep Sleep, and Hibernate power modes. The MCWDTs are clocked by LFCLK (ILO or WCO). It can generate periodic interrupt/wakeup in system LP/ULP and Deep Sleep power modes.

Clock Dividers

Integer and fractional clock dividers are provided for peripheral use and timing purposes. There are:

- Four 8-bit clock dividers
- Eight 16-bit integer clock dividers
- Two 16.5-bit fractional clock dividers
- One 24.5-bit fractional clock divider

Trigger Routing

PSoC 6 MCU contains a trigger multiplexer block. This is a collection of digital multiplexers and switches that are used for routing trigger signals between peripheral blocks and between GPIOs and peripheral blocks.

There are two types of trigger routing. Trigger multiplexers have reconfigurability in the source and destination. There are also hardwired switches called “one-to-one triggers”, which connect a specific source to a destination. The user can enable or disable the route.

Reset

PSoC 6 MCU can be reset from a variety of sources:

- Power-on reset (POR) to hold the device in reset while the power supply ramps up to the level required for the device to function properly. POR activates automatically at power-up.
- Brown-out detect (BOD) reset to monitor the digital voltage supply V_{DD} and generate a reset if V_{DD} falls below the minimum required logic operating voltage.
- External reset dedicated pin (XRES) to reset the device using an external source. The XRES pin is active low. It can be connected either to a pull-up resistor to V_{DD} , or to an active drive circuit, as Figure 5 shows. If a pull-up resistor is used, select its value to minimize current draw when the pin is pulled low; 4.7 kΩ is typical.

Figure 5. XRES Connection Diagram

- Watchdog timer (WDT or MCWDT) to reset the device if firmware fails to service it within a specified timeout period.
- Software-initiated reset to reset the device on demand using firmware.
- Logic-protection fault can trigger an interrupt or reset the device if unauthorized operating conditions occur; for example, reaching a debug breakpoint while executing privileged code.
- Hibernate wakeup reset to bring the device out of the system Hibernate power mode.

Reset events are asynchronous and guarantee reversion to a known state. Some of the reset sources are recorded in a register, which is retained through reset and allows software to determine the cause of the reset.

Programmable Analog Subsystems

12-bit SAR ADC

The 12-bit, 2-Msps SAR ADC can operate at a maximum clock rate of 36 MHz and requires a minimum of 18 clocks at that frequency to do a 12-bit conversion. One of three internal reference voltages may be used for the ADC reference voltage. The references are, V_{DD} , $V_{DD}/2$, and V_{REF} (nominally 1.2 V and trimmed to $\pm 1\%$). An external reference may also be used, by either driving the VREF pin or routing an external reference to GPIO pin P9.3. These reference options allow ratio-metric readings or absolute readings at the accuracy of the reference used. The input range of the ADC is the full supply voltage between V_{SS} and V_{DDA}/V_{DDIOA} . The SAR ADC may be configured with a mix of single-ended and differential signals in the same configuration.

The SAR ADC's sample-and-hold (S/H) aperture is programmable to allow sufficient time for signals with a high impedance to settle sufficiently, if required. System performance is 65 dB for true 12-bit precision provided appropriate references are used and system noise levels permit it. To improve performance in noisy conditions, an external bypass capacitor for the internal reference amplifier (through the fixed “VREF” pin), may be added.

The SAR is connected to a fixed set of pins through an input multiplexer. The multiplexer cycles through the selected channels autonomously (sequencer scan) and does so with zero switching overhead (that is, the aggregate sampling bandwidth is equal to 2 Msps whether it is for a single channel or distributed over several channels). The result of each channel is buffered, so that an interrupt may be triggered only when a full scan of all channels is complete. Also, a pair of range registers can be set to detect and cause an interrupt if an input exceeds a minimum and/or maximum value. This allows fast detection of out-of-range values without having to wait for a sequencer scan to be completed and the CPU to read the values and check for out-of-range values in software. The SAR can also be connected, under firmware control, to most other GPIO pins via the Analog Multiplexer Bus (AMUXBUS). The SAR is not available in system Deep Sleep and Hibernate modes as it requires a high-speed clock (up to 36 MHz). The SAR operating range is 1.71 to 3.6 V.

Temperature Sensor

An on-chip temperature sensor is part of the SAR and may be scanned by the SAR ADC. It consists of a diode, which is biased by a current source that can be disabled to save power. The temperature sensor may be connected directly to the SAR ADC as one of the measurement channels. The ADC digitizes the temperature sensor's output and a Cypress-supplied software function may be used to convert the reading to temperature which includes calibration and linearization.

Low-Power Comparators

Two low-power comparators are provided, which can operate in all power modes. This allows other analog system resources to be disabled while retaining the ability to monitor external voltage levels during system Deep Sleep and Hibernate modes. The comparator outputs are normally synchronized to avoid metastability unless operating in an asynchronous power mode (Hibernate) where the system wake-up circuit is activated by a comparator-switch event.

Figure 6 shows an overview of the analog subsystem. This diagram is a high-level abstraction. See the [TRM](#) for detailed connectivity information.

Figure 6. Analog Subsystem

Programmable Digital

Smart I/O

Smart I/O is a programmable logic fabric that enables Boolean operations on signals traveling from device internal resources to the GPIO pins or on signals traveling into the device from external sources. A Smart I/O block sits between the GPIO pins and the high-speed I/O matrix (HSIOM) and is dedicated to a single port.

There are two Smart I/O blocks: one on Port 8 and one on Port 9. When Smart I/O is not enabled, all signals on Port 8 and Port 9 bypass the Smart I/O hardware.

Smart I/O supports:

- System Deep Sleep operation
- Boolean operations without CPU intervention
- Asynchronous or synchronous (clocked) operation

Each Smart I/O block contains a data unit (DU) and eight lookup tables (LUTs).

The DU:

- Performs unique functions based on a selectable opcode.
- Can source input signals from internal resources, the GPIO port, or a value in the DU register.

Each LUT:

- Has three selectable input sources. The input signals may be sourced from another LUT, an internal resource, an external signal from a GPIO pin, or from the DU.
- Acts as a programmable Boolean logic table.
- Can be synchronous or asynchronous.

Fixed-Function Digital

Timer/Counter/Pulse-width Modulator (TCPWM)

- The TCPWM supports the following operational modes:
 - Timer-counter with compare
 - Timer-counter with capture
 - Quadrature decoding
 - Pulse width modulation (PWM)
 - Pseudo-random PWM
 - PWM with dead time
- Up, down, and up/down counting modes.
- Clock prescaling (division by 1, 2, 4, ... 64, 128)
- Double buffering of compare/capture and period values
- Underflow, overflow, and capture/compare output signals
- Supports interrupt on:
 - Terminal count – Depends on the mode; typically occurs on overflow or underflow
 - Capture/compare – The count is captured to the capture register or the counter value equals the value in the compare register
- Complementary output for PWMs
- Selectable start, reload, stop, count, and capture event signals for each TCPWM; with rising edge, falling edge, both edges, and level trigger options. The TCPWM has a Kill input to force outputs to a predetermined state.

In this device there are:

- Four 32-bit TCPWMs
- Eight 16-bit TCPWMs

Serial Communication Blocks (SCB)

This product line has seven SCBs:

- Six can implement either I²C, UART, or SPI.
- One SCB (SCB #6) can operate in system Deep Sleep mode with an external clock; this SCB can be either SPI slave or I²C slave.

I²C Mode: The SCB can implement a full multi-master and slave interface (it is capable of multimaster arbitration). This block can operate at speeds of up to 1 Mbps (Fast Mode Plus). It also supports EZI²C, which creates a mailbox address range and effectively reduces I²C communication to reading from and writing to an array in memory. The SCB supports a 256-byte FIFO for receive and transmit.

The I²C peripheral is compatible with I²C standard-mode, Fast Mode, and Fast Mode Plus devices as defined in the NXP I²C-bus specification and user manual (UM10204). The I²C bus I/O is implemented with GPIO in open-drain modes.

UART Mode: This is a full-feature UART operating at up to 8 Mbps. It supports automotive single-wire interface (LIN), infrared interface (IrDA), and SmartCard (ISO7816) protocols, all of which are minor variants of the basic UART protocol. In addition, it supports the 9-bit multiprocessor mode that allows the addressing of peripherals connected over common RX and TX lines. Common UART functions such as parity error, break detect, and frame error are supported. A 256-byte FIFO allows much greater CPU service latencies to be tolerated.

SPI Mode: The SPI mode supports full Motorola SPI, TI Secure Simple Pairing (SSP) (essentially adds a start pulse that is used to synchronize SPI Codecs), and National Microwire (half-duplex form of SPI). The SPI block supports an EZSPI mode in which the data interchange is reduced to reading and writing an array in memory. The SPI interface operates with a 25-MHz clock.

USB Full-Speed Device Interface

This product line incorporates a full-speed USB device interface. The device can have up to eight endpoints. A 512-byte SRAM buffer is provided and DMA is supported.

Note: If the USB pins are not used, connect V_{DDUSB} to ground and leave the P14.0/USBDP and P14.1/USBDM pins unconnected.

Quad-SPI/Serial Memory Interface (SMIF)

A serial memory interface is provided, running at up to 80 MHz. It supports single, dual, and quad SPI configurations, and supports up to four external memory devices. It supports two modes of operation:

- Memory-mapped I/O (MMIO), a command mode interface that provides data access via registers and FIFOs
- Execute in Place (XIP), in which AHB reads and writes are directly translated to SPI read and write transfers.

In XIP mode, the external memory is mapped into the PSoC 6 MCU internal address space, enabling code execution directly from the external memory. To improve performance, a 4-KB cache is included. XIP mode also supports AES-128 on-the-fly encryption and decryption, enabling secured storage and access of code and data in the external memory.

LCD

This block drives LCD commons and segments; routing is available to most of the GPIOs. One to eight of the GPIOs must be used for commons, the rest can be used for segments.

The LCD block has two modes of operation: high speed (8 MHz) and low speed (32 kHz). Both modes operate in system LP, ULP, and Deep Sleep modes, however the low-speed mode operates with reduced contrast in system Deep Sleep mode. The 8-MHz IMO is available in system Deep Sleep mode, and can be used to generate a clock for the LCD block. Review the number of common and segment lines, viewing angle requirements, and prototype performance, and then select the appropriate LCD clock frequency before using system Deep Sleep mode.

SD Host Controller

This product line contains one Secure Digital (SD) host controller. It provides communication with IoT connectivity devices such as Bluetooth, Bluetooth Low-Energy and WiFi radios, as well as combination devices. The controller also supports embedded MultiMediaCards (eMMC) and Secure Digital (SD) cards.

Several bus speed modes under the SD specification are supported:

- DS (default speed)
- HS (high speed)
- SDR12 (single data rate)
- SDR25

■ SDR50

■ DDR50 (double data rate)

For eMMC, the supported modes are:

■ BWC (backward compatibility)

■ SDR

Maximum clock restrictions and capacitive loads apply to some modes, and are also dependent on system power mode (LP/ULP). Refer to the [SD Host Controller and eMMC Specifications](#) for details.

The SD Host Controller complies with the following standards. Refer to the specifications documents for more information on the protocol and operations.

■ SD Specifications Part 1 Physical Layer Specification Version 6.00, supporting card capacities for SDSC (up to 2 GB), SDHC (up to 32 GB) and SDXC (up to 2 TB).

■ SD Specifications Part A2 SD Host Controller Standard Specification Version 4.20

■ SD Specifications Part E1 SDIO Specifications Version 4.10

■ Embedded Multi-Media Card (eMMC) Electrical Standard 5.1

The SD host controller is configured as a master. To be fully compatible with features provided in the driver software for speed and efficiency, it supports advanced DMA version 3 (ADMA3), defined by the SDIO standard, and has a 1 KB RX/TX FIFO allowing double buffering of 512-byte blocks.

CAN FD Block

This product line has one CAN FD block for industrial and automotive applications. The block includes Time-Stamp support and has a 4-KB message RAM. FD Data rates of up to 5 Mbps are supported. DMA transfers are supported.

GPIO

This product line has up to 53 GPIOs, which implement the following:

■ Eight drive strength modes:

- Analog input mode (input and output buffers disabled)
- Input only
- Weak pull-up with strong pull-down
- Strong pull-up with weak pull-down

- Open drain with strong pull-down

- Open drain with strong pull-up

- Strong pull-up with strong pull-down

- Weak pull-up with weak pull-down

■ Input threshold select (CMOS or LVTTL)

■ Hold mode for latching previous state (used for retaining the I/O state in system Hibernate mode)

■ Selectable slew rates for dV/dt-related noise control to improve EMI

The pins are organized in logical entities called ports, which are up to 8 pins in width. Data output and pin state registers store, respectively, the values to be driven on the pins and the input states of the pins.

Every pin can generate an interrupt if enabled; each port has an interrupt request (IRQ) associated with it.

The port 3 pins are capable of overvoltage-tolerant (OVT) operation, where the input voltage may be higher than V_{DD} . OVT pins are commonly used with I²C, to allow powering the chip OFF while maintaining a physical connection to an operating I²C bus without affecting its functionality.

GPIO pins can be ganged to source or sink higher values of current. GPIO pins, including OVT pins, may not be pulled up higher than the absolute maximum; see [Electrical Specifications](#).

During power-on and reset, the pins are forced to the analog input drive mode, with input and output buffers disabled, so as not to crowbar any inputs and/or cause excess turn-on current.

A multiplexing network known as the high-speed I/O matrix (HSIOM) is used to multiplex between various peripheral and analog signals that may connect to an I/O pin.

Analog performance is affected by GPIO switching noise. In order to get the best analog performance, the following frequency and drive mode constraints must be applied. The DRIVE_SEL values (see [Table 6](#)) represent drive strengths (please see the [Architecture and Register TRMs](#) for further detail).

See also [Table 5](#) for additional restrictions for ECO use.

Table 6. DRIVE_SEL Values

Ports	Max Frequency	Drive Strength for $V_{DD} \leq 2.7$ V	Drive Strength for $V_{DD} > 2.7$ V
Ports 0, 1	8 MHz	DRIVE_SEL 2	DRIVE_SEL 3
Port 2	50 MHz	DRIVE_SEL 1	DRIVE_SEL 2
Ports 3 to 10	16 MHz; 25 MHz for SPI	DRIVE_SEL 2	DRIVE_SEL 3
Ports 11 to 12	80 MHz for SMIF (QSPI).	DRIVE_SEL 1	DRIVE_SEL 2
Ports 9 and 10	Slow slew rate setting for TQFP Packages for ADC performance	No restrictions	No restrictions

Special-Function Peripherals

CapSense Subsystem

CapSense is supported in PSoC 6 MCU through a CapSense sigma-delta (CSD) hardware block. It is designed for high-sensitivity self-capacitance and mutual-capacitance measurements, and is specifically built for user interface solutions.

In addition to CapSense, the CSD hardware block supports three general-purpose functions. These are available when CapSense is not being used. Alternatively, two or more functions can be time-multiplexed in an application under firmware control. The four functions supported by the CSD hardware block are:

- CapSense
- 10-bit ADC
- Programmable current sources (IDAC)
- Comparator

CapSense

Capacitive touch sensors are designed for user interfaces that rely on human body capacitance to detect the presence of a finger on or near a sensor. Cypress CapSense solutions bring elegant, reliable, and simple capacitive touch sensing functions to applications including IoT, industrial, automotive, and home appliances.

The Cypress-proprietary CapSense technology offers the following features:

- Best-in-class signal-to-noise ratio (SNR) and robust sensing under harsh and noisy conditions
- Self-capacitance (CSD) and mutual-capacitance (CSX) sensing methods
- Support for various widgets, including buttons, matrix buttons, sliders, touchpads, and proximity sensors
- High-performance sensing across a variety of materials
- Best-in-class liquid tolerance
- SmartSense™ auto-tuning technology that helps avoid complex manual tuning processes
- Superior immunity against external noise
- Spread-spectrum clocks for low radiated emissions
- Gesture and built-in self-test libraries
- Ultra-low power consumption
- An integrated graphical CapSense tuner for real-time tuning, testing, and debugging

ADC

The CapSense subsystem slope ADC offers the following features:

- Selectable 8- or 10-bit resolution
- Selectable input range: GND to V_{REF} and GND to V_{DDA} on any GPIO input
- Measurement of V_{DDA} against an internal reference without the use of GPIO or external components

IDAC

The CSD block has two programmable current sources, which offer the following features:

- 7-bit resolution
- Sink and source current modes
- A current source programmable from 37.5 nA to 609 μ A
- Two IDACs that can be used in parallel to form one 8-bit IDAC

Comparator

The CapSense subsystem comparator operates in the system Low Power and Ultra-Low Power modes. The inverting input is connected to an internal programmable reference voltage and the non-inverting input can be connected to any GPIO via the AMUXBUS.

CapSense Hardware Subsystem

Figure 7 shows the high-level hardware overview of the CapSense subsystem, which includes a delta sigma converter, internal clock dividers, a shield driver, and two programmable current sources.

The inputs are managed through analog multiplexed buses (AMUXBUS A/B). The input and output of all functions offered by the CSD block can be provided on any GPIO or on a group of GPIOs under software control, with the exception of the comparator output and external capacitors that use dedicated GPIOs.

Self-capacitance is supported by the CSD block using AMUXBUS A, an external modulator capacitor, and a GPIO for each sensor. There is a shield electrode (optional) for self-capacitance sensing. This is supported using AMUXBUS B and an optional external shield tank capacitor (to increase the drive capability of the shield driver) should this be required. Mutual-capacitance is supported by the CSD block using AMUXBUS A, two external integrated capacitors, and a GPIO for transmit and receive electrodes.

The ADC does not require an external component. Any GPIO that can be connected to AMUXBUS A can be an input to the ADC under software control. The ADC can accept V_{DDA} as an input without needing GPIOs (for applications such as battery voltage measurement).

The two programmable current sources (IDACs) in general-purpose mode can be connected to AMUXBUS A or B. They can therefore connect to any GPIO pin. The comparator resides in the delta-sigma converter. The comparator inverting input can be connected to the reference. Both comparator inputs can be connected to any GPIO using AMUXBUS B; see Figure 6. The reference has a direct connection to a dedicated GPIO; see Table 9.

The CSD block can operate in active and sleep CPU power modes, and seamlessly transition between system LP and ULP modes. It can be powered down in system Deep Sleep and Hibernate modes. Upon wakeup from Hibernate mode, the CSD block requires re-initialization. However, operation can be resumed without re-initialization upon exit from Deep Sleep mode, under firmware control.

Figure 7. CapSense Hardware Subsystem

Figure 18 shows the high-level software overview. Cypress provides middleware libraries for [CapSense](#), [ADC](#), and [IDAC](#) on GitHub to enable quick integration. The Board Support Package for any kit with CapSense capabilities automatically includes the CapSense library in any application that uses the BSP.

User applications interact only with middleware to implement functions of the CSD block. The middleware interacts with underlying drivers to access hardware as necessary. The CSD driver facilitates time-multiplexing of the CSD hardware if more than one piece of CSD-related middleware is present in a project. It prevents access conflicts in this case.

ModusToolbox Software provides a CapSense configurator to enable fast library configuration. It also provides a tuner for performance evaluation and real-time tuning of the system. The tuner requires an EZI2C communication interface in the application to enable real-time tuning capability. The tuner can update configuration parameters directly in the device as well as in the configurator.

CapSense and ADC middleware use the CSD interrupt to implement non-blocking sensing and A-to-D conversion. Therefore, interrupt service routines are a defined part of the middleware, which must be initialized by the application. Middleware and drivers can operate on either CPU. Cypress recommends using the middleware only in one CPU. If both CPUs must access the CSD driver, memory access should be managed in the application.

Refer to [AN85951: PSoC 4 and PSoC 6 MCU CapSense Design Guide](#) for more details on CSX sensing, CSD sensing, shield electrode usage and its benefits, and capacitive system design guidelines.

Refer to the API reference guides for [CapSense](#), [ADC](#), and [IDAC](#) available on GitHub.

PSoC 64 Security

All PSoC 64 “Secure” MCU product lines feature enhanced security functionality. They provide an isolated root of trust (RoT) with true attestation and provisioning services. Cypress also provides a “Secure Boot” SDK which includes all required libraries, tools, and sample code to provision PSoC 64 devices. The SDK also provides provisioning scripts with sample keys and policies, a pre-built bootloader image, and tools for signing firmware images. For more information, see the “[Secure Boot SDK User Guide](#)”.

The “Secure Boot” SDK also includes entrance exam scripts. An entrance exam can optionally be run on PSoC 64 devices before provisioning to ensure that no device tampering has occurred.

The first step in using a PSoC 64 device is to inject the following information into the device - a process called provisioning:

- A set of cryptographic public keys, which are used to:
 - Transfer the RoT from Cypress to the user/OEM, as [Figure 9](#) shows
 - Validate applications
- A set of security policies that define how the device should behave
- Certificates (optional) used to bind device identity or provide a chain of trust to a higher certifying authority
- The Cypress bootloader

Provisioning is done before an application is programmed into the device.

Figure 9. PSoC 64 Usage Processes

Provisioning is done using a hardware security module (HSM). An HSM is a physical computing device, placed in a secured facility, that safeguards and manages digital keys for strong authentication, and provides cryptographic processing.

After the device is provisioned, it can be programmed with signed applications. The signature and authenticity of the application is verified before control is transferred to it.

Figure 10 shows a simplified flash memory map of PSoC 64 assets and immutable sections. As noted in [Memory](#), a portion of device SRAM is also reserved for system usage.

Figure 10. PSoC 64 “Secure” MCU Asset Memory Map

Cypress Bootloader

Cypress Bootloader is a port of the open source [MCUBoot](#) library. For more details about this library, refer to [MCUBoot Bootloader design](#). The current version of Cypress Bootloader for this device does not support the swap-based images feature as documented in the MCUBoot design document.

Cypress Bootloader is included in the “[Secure Boot](#)” SDK as a pre-built hex image. This image acts as the first image launched by the PSoC 64 boot code. It parses the provisioned Boot&Upgrade policy to launch an application image.

Cypress Bootloader supports external memory over the PSoC 64 Serial Memory Interface (SMIF). The bootloader currently supports only external memory vendors who support the Serial Flash Discovery Protocol (SFDP).

Cypress Bootloader enforces protection contexts for the bootloader code, so code running in another protection context cannot overwrite/tamper with the bootloader code. [Figure 11](#) shows the launch sequence of Cypress Bootloader:

Figure 11. Bootloader Launch Sequence

[Figure 12](#) shows a typical application update scenario using Cypress Bootloader:

Pinouts

Note: The CYB06445LQI-S3D42 [datasheet web page](#) contains a spreadsheet with a consolidated list of pinouts and pin alternate functions with HSIOM mapping. GPIO ports are powered by V_{DDx} pins as follows:

- P0: V_{BACKUP}
- P2, P3: V_{DDIO2}
- P5, P6, P7, P8: V_{DDIO1}
- P9, P10: V_{DDIOA} , V_{DDA} (V_{DDIOA} and V_{DDA} must be connected together on the PCB)
- P11, P12: V_{DDIO0}
- P14: V_{DDUSB}

 2. The center pad on the QFN package should be connected to PCB ground relative to device VDDx for best mechanical, thermal, and electrical performance. For more information, see [AN72845](#), Design Guidelines for QFN Devices.

Each port pin has multiple alternate functions. These are defined in Table 8. The columns ACT #x and DS #y denote active (System LP/ULP) and Deep Sleep mode signals respectively.

The notation for a signal is of the form IPName[x].signal_name[u]:y.

IPName = Name of the block (such as tcpwm), x = Unique instance of the IP, Signal_name = Name of the signal, u = Signal number where there is more than one signal for a particular signal name, y = Designates copies of the signal name.

For example, the name tcpwm[0].line_compl[3]:4 indicates that this is instance 0 of a tcpwm block, the signal is line_compl # 3 (complement of the line output) and this is the fourth occurrence (copy) of the signal. Signal copies are provided to allow flexibility in routing and to maximize use of on-chip resources.

Power Supply Considerations

The following power system diagrams show typical connections for power pins, with and without usage of the buck regulator.

In these diagrams, the package pin is shown with the pin name, for example "V_{DDA}, 36". For V_{DDx} pins, the I/O port that is powered by that pin is also shown, for example "V_{BACKUP}, 1; I/O port P0".

In the QFN package, all internal grounds are routed to the metal pad (epad) in the package. This pad must be grounded on the PCB.

Figure 14. 68-QFN Power Connections Diagram

Figure 15. 68-QFN (No Buck) Power Connections Diagram

There are as many as eight V_{DDx} supply pins, depending on the package, and multiple V_{SS} ground pins. The power pins are:

- V_{DD} : the main digital supply. It powers the LDO and switching regulators.
- V_{CCD} : the main LDO output. It requires a 4.7-µF capacitor for regulation. The LDO can be turned off when V_{CCD} is driven from the switching regulator (see below). For more information, see the power system block diagram in the device [technical reference manual \(TRM\)](#).
- V_{DDA} : the supply for the analog peripherals. Voltage must be applied to this pin for correct device initialization and boot up.
- V_{DDIOA} : the supply for I/O ports 9 and 10. It must be connected to V_{DDA} .
- V_{DDIO0} : the supply for I/O ports 11 and 12.
- V_{DDIO1} : the supply for I/O ports 5, 6, 7, and 8.
- V_{DDIO2} : the supply for I/O ports 2 and 3.

- V_{BACKUP} : the supply for the backup domain, which includes the 32-kHz WCO and the RTC. It can be a separate supply as low as 1.4 V, for battery or supercapacitor backup, as [Figure 16](#) shows, otherwise it is connected to V_{DD} . It powers I/O port 0.

Figure 16. Separate Battery Connection to V_{BACKUP}

- V_{DDUSB} : the supply for the USB peripheral and the USBDP and USBDM pins. It must be 2.85 V to 3.6 V for USB operation. If USB is not used, it can be 1.7 V to 3.6 V, and the USB pins can be used as limited-capability GPIOs on I/O port 14.

Table 10 shows a summary of the I/O port supplies:

Table 10. I/O Power Supplies

Port	Supply	Alternate Supply
0	V _{BACKUP}	V _{DDD}
2, 3	V _{DDIO2}	—
5, 6, 7, 8	V _{DDIO1}	—
9, 10	V _{DDIOA}	V _{DDA}
11, 12	V _{DDIO0}	—
14	V _{DDUSB}	—

Note: If the USB pins are not used, connect V_{DDUSB} to ground and leave the P14.0/USBDP and P14.1/USBDM pins unconnected.

Voltage must be applied to the V_{DDD} pin, and the V_{DDA} pin as noted above, for correct device initialization and operation. If an I/O port is not being used, applying voltage to the corresponding V_{DDx} pin is optional.

- V_{SS}: ground pins for the above supplies. All ground pins should be connected together to a common ground.

In addition to the LDO regulator, a switching regulator is included. The regulator pins are:

- V_{DD_NS}: the regulator supply.
- V_{IND1}: the regulator output. It is typically used to drive V_{CCD} through an inductor.

The V_{DD} power pins are not connected on chip. They can be connected off chip, in one or more separate nets. If separate power nets are used, they can be isolated from noise from the other nets using optional ferrite beads, as indicated in the diagrams.

No external load should be placed on V_{CCD}, or V_{IND1}, whether or not these pins are used.

There are no power pin sequencing requirements; power supplies may be brought up in any order. The power management system holds the device in reset until all power pins are at the voltage levels required for proper operation.

Note: If a battery is installed on the PCB first, V_{DDD} must be cycled for at least 50 μ s. This prevents premature drain of the battery during product manufacture and storage.

Bypass capacitors must be connected to a common ground from the V_{DDx} and other pins, as indicated in the diagrams. Typical practice for systems in this frequency range is to use a 10- μ F or 1- μ F capacitor in parallel with a smaller capacitor (0.1 μ F, for example). Note that these are simply rules of thumb and that, for critical applications, the PCB layout, lead inductance, and bypass capacitor parasitic should be simulated for optimal bypassing.

All capacitors and inductors should be $\pm 20\%$ or better. The recommended inductor value is 2.2 μ H $\pm 20\%$ (for example, TDK MLP2012H2R2MT0S1).

It is good practice to check the datasheets for your bypass capacitors, specifically the working voltage and the DC bias specifications. With some capacitors, the actual capacitance can decrease considerably when the applied voltage is a significant percentage of the rated working voltage.

For more information on pad layout, refer to [PSoC 6 CAD libraries](#).

Electrical Specifications

All specifications are valid for $-40\text{ }^{\circ}\text{C} \leq T_A \leq 85\text{ }^{\circ}\text{C}$ and for 1.71 V to 3.6 V except where noted.

Device-Level Specifications

Table 14 provides detailed specifications of CPU current. Table 12 summarizes these specifications, for rapid review of CPU currents under common conditions. Note that the max frequency for CM4 is 150 MHz, and for CM0+ is 100 MHz. IMO and FLL are used to generate the CPU clocks; FLL is not used when the CPU clock frequency is 8 MHz.

CM4 active, CM0+ sleep	Across CPUs clock ranges: 8 – 50/25 MHz; Dhrystone with flash cache enabled	0.65–1.6 mA	0.8–2.2mA
CM0+ active, CM4 sleep		0.51–0.91 mA	0.72–1.25 mA
CM4 sleep, CM0+ sleep		0.42–0.76 mA	0.65–1.1 mA
CM0+ sleep, CM4 off		0.41–0.62 mA	0.6–0.9 mA
Minimum regulator current mode	Across CM4/CM0+ CPU active/sleep modes	0.39–0.54 mA	0.6–0.76 mA
Deep Sleep	Across SRAM retention	7–9 μA	-
Hibernate	Across V _{DD}	300–800 nA	-

Note

- Usage above the absolute maximum conditions listed in Table 11 may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods of time may affect device reliability. The maximum storage temperature is $150\text{ }^{\circ}\text{C}$ in compliance with JEDEC Standard JESD22-A103, High Temperature Storage Life. When used below absolute maximum conditions but above normal operating conditions, the device may not operate to specification.

Note

4. It can take as much as 16 milliseconds to write to flash. During this time, the device should not be reset, or flash operations will be interrupted and cannot be relied on to have completed. Reset sources include the XRES pin, software resets, CPU lockup states and privilege violations, improper power supply levels, and watchdogs. Make certain that these are not inadvertently activated.

Acronyms

Acronym	Description
3DES	triple DES (data encryption standard)
ADC	analog-to-digital converter
ADMA3	advanced DMA version 3, a Secure Digital data transfer mode
AES	advanced encryption standard
AHB	AMBA (advanced microcontroller bus architecture) high-performance bus, an Arm data transfer bus
AMUX	analog multiplexer
AMUXBUS	analog multiplexer bus
API	application programming interface
Arm®	advanced RISC machine, a CPU architecture
BGA	ball grid array
BOD	brown-out detect
BREG	backup registers
BWC	backward compatibility (eMMC data transfer mode)
CAD	computer aided design
CCO	current controlled oscillator
ChaCha	a stream cipher
CM0+	Cortex-M0+, an Arm CPU
CM4	Cortex-M4, an Arm CPU
CMAC	cypher-based message authentication code
CMOS	complementary metal-oxide-semiconductor, a process technology for IC fabrication
CMRR	common-mode rejection ratio
CPU	central processing unit
CRC	cyclic redundancy check, an error-checking protocol
CSD	CapSense Sigma-Delta
CSV	clock supervisor
CSX	Cypress mutual capacitance sensing method. See also CSD
CTI	cross trigger interface
DAC	digital-to-analog converter, see also IDAC, VDAC
DAP	debug access port
DDR	double data rate
DES	data encryption standard
DFT	design for test
DMA	direct memory access, see also TD
DNL	differential nonlinearity, see also INL
DSI	digital system interconnect
DU	data unit
DW	data wire, a DMA implementation

Acronym	Description
ECC	error correcting code
ECC	elliptic curve cryptography
ECO	external crystal oscillator
EEPROM	electrically erasable programmable read-only memory
EMI	electromagnetic interference
eMMC	embedded MultiMediaCard
ESD	electrostatic discharge
ETM	embedded trace macrocell
FIFO	first-in, first-out
FLL	frequency locked loop
FPU	floating-point unit
FS	full-speed
GND	Ground
GPIO	general-purpose input/output, applies to a PSoC pin
HMAC	Hash-based message authentication code
HSIOM	high-speed I/O matrix
I/O	input/output, see also GPIO, DIO, SIO, USBIO
I ² C, or IIC	Inter-Integrated Circuit, a communications protocol
I ² S	inter-IC sound
IC	integrated circuit
IDAC	current DAC, see also DAC, VDAC
IDE	integrated development environment
ILO	internal low-speed oscillator, see also IMO
IMO	internal main oscillator, see also ILO
INL	integral nonlinearity, see also DNL
IOSS	input output subsystem
IoT	internet of things
IPC	inter-processor communication
IRQ	interrupt request
ISR	interrupt service routine
ITM	instrumentation trace macrocell
JTAG	Joint Test Action Group
LCD	liquid crystal display
LIN	Local Interconnect Network, a communications protocol
LP	low power
LS	low-speed
LUT	lookup table
LVD	low-voltage detect, see also LVI
LVI	low-voltage interrupt
LVTTTL	low-voltage transistor-transistor logic

Acronym	Description
MAC	multiply-accumulate
MCU	microcontroller unit
MISO	master-in slave-out
MMIO	memory-mapped input output
MOSI	master-out slave-in
MPU	memory protection unit
MSL	moisture sensitivity level
Msp/s	million samples per second
MTB	micro trace buffer
MUL	multiplier
NC	no connect
NMI	nonmaskable interrupt
NVIC	nested vectored interrupt controller
NVL	nonvolatile latch, see also WOL
OTP	one-time programmable
OVP	over voltage protection
OVT	overvoltage tolerant
PASS	programmable analog subsystem
PCB	printed circuit board
PCM	pulse code modulation
PDM	pulse density modulation
PHY	physical layer
PICU	port interrupt control unit
PLL	phase-locked loop
PMIC	power management integrated circuit
POR	power-on reset
PPU	peripheral protection unit
PRNG	pseudo random number generator
PSoC®	Programmable System-on-Chip™
PSRR	power supply rejection ratio
PWM	pulse-width modulator
QD	quadrature decoder
QSPI	quad serial peripheral interface
RAM	random-access memory
RISC	reduced-instruction-set computing
RMS	root-mean-square
ROM	read-only memory
RSA	Rivest–Shamir–Adleman, a public-key cryptography algorithm
RTC	real-time clock
RWW	read-while-write
RX	receive
S/H	sample and hold

Acronym	Description
SAR	successive approximation register
SARMUX	SAR ADC multiplexer bus
SC/CT	switched capacitor/continuous time
SCB	serial communication block
SCL	I ² C serial clock
SD	Secure Digital
SDA	I ² C serial data
SDHC	Secure Digital host controller
SDR	single data rate
Sflash	supervisory flash
SHA	secure hash algorithm
SINAD	signal to noise and distortion ratio
SMPU	shared memory protection unit
SNR	signal-to-noise ration
SOF	start of frame
SONOS	silicon-oxide-nitride-oxide-silicon, a flash memory technology
SPI	Serial Peripheral Interface, a communications protocol
SRAM	static random access memory
SROM	supervisory read-only memory
SRSS	system resources subsystem
SWD	serial wire debug, a test protocol
SWJ	serial wire JTAG
SWO	single wire output
SWV	single-wire viewer
TCPWM	timer, counter, pulse-width modulator
TDM	time division multiplexed
THD	total harmonic distortion
TQFP	thin quad flat package
TRM	technical reference manual
TRNG	true random number generator
TX	transmit
UART	Universal Asynchronous Transmitter Receiver, a communications protocol
ULP	ultra-low power
USB	Universal Serial Bus
WCO	watch crystal oscillator
WDT	watchdog timer
WIC	wakeup interrupt controller
WLCSP	wafer level chip scale package
XIP	execute-in-place
XRES	external reset input pin

Errata Summary

This table defines the errata applicability to available PSoC 6 CYB06445LQI-S3D42 devices.

Items	PSoC CYB06445LQI-S3D42	Silicon Revision	Fix Status
[1.] DMA controllers are not available	All	Production silicon	Resolution planned by Q4 '22

1. DMA controllers are not available	
Problem Definition	The 32- and 29-channel DMA controllers are not available. Register access to these controllers is not available. The 2-channel controller is available; there are no USB or audio connections to it.
Parameters Affected	The 32- and 29-channel DMA controllers
Trigger Condition(s)	Attempt to use the 32- or the 29-channel DMA controller, by accessing their registers
Scope of Impact	CPU exceptions are generated
Workaround	Use the 2-channel controller for DMA operations
Fix Status	Investigation underway. Fix planned by Q3'21.

Revision History

Description Title: PSoC 6 MCU: CYB06445LQI-S3D42 Datasheet Document Number: 002-28785			
Revision	ECN	Submission Date	Description of Change
**	6711017	10/22/2019	New datasheet.
*A	6776273	01/16/2020	Updated Features . Updated Blocks and Functionality and Functional Description . Updated Pinouts and Power Supply Considerations . Updated Packaging .
*B	6851682	04/10/2020	Updated Features . Updated Functional Description . Updated Pinouts . Updated PSoC 6 MPN Decoder .
*C	6894902	06/16/2020	Updated Development Ecosystem , GPIO , and LCD sections. Added External Crystal Oscillators . Updated Revision History
*D	6981432	11/16/2020	Updated Flexible Clocking Options , Block Diagram , and CPUs . Updated list of application notes and links and the kit link in PSoC 6 MCU Resources . Updated the amount of available SRAM in Features , Blocks and Functionality , Memory , Table 3 , and Ordering Information . Updated the PSoC 64 Security section. Updated ModusToolbox Software . Updated Quad-SPI (QSPI)/Serial Memory Interface (SMIF) . Added InterProcessor Communication (IPC) . Updated Analog Subsystem diagram. Updated Direct Memory Access (DMA) Controllers . Updated VDDA bullet in Power Supply Considerations . Updated the XRES bullet in Reset , SID15 Description and Conditions , and System Resources (Power-On-Reset specifications) Updated SID7A conditions, SID7D description, and SID8 conditions. Updated SD Host Controller and eMMC Specifications . Integrated ECO erratum into External Crystal Oscillators . Added ECO Usage Guidelines table. Added Errata items.
*E	7139142	05/13/2021	Updated Security terminology to Infineon standards. Changed BLE references to Bluetooth LE. Added Table 14 and Figure 33 in Electrical Specifications. Removed SIDD1 and SIDD1_B and updated Typ values for SIDD2 and SIDD2_B Added "DMA controllers are not available" errata item.
*F	7231613	08/20/2021	Updated SIDD2 - Corrected Deep Sleep current values. Removed "System Deep Sleep power higher than specification" errata item.
*G	7487079	12/03/2021	Removed Preliminary tag from the datasheet. Updated Figure 6 . Added note regarding unused USB pins in USB Full-Speed Device Interface , Power Supply Considerations , and Pinouts . Updated SIDC1 description. Updated details/conditions for SID7A . Updated SID325U , SID328 , and SID329 description. Updated Errata .
*H	7758801	05/05/2022	Corrected typo in Figure 14 and Figure 15 .
